Let's test our collective intuition:

Money
 \equiv
 Belief

Two questions about wealth distribution in the United States:

1. Please estimate the percentage of all wealth owned by individuals when grouped into quintiles.
2. Please estimate what you believe each quintile should own, ideally.
3. Extremes: 100, 0, 0, 0, 0 and 20, 20, 20, 20, 20

- CCDFs
- Zipf's law
- Zipf ↔ CCDF
- References

Size distributions:

Many systems have discrete sizes k :

- ▶ Word frequency
- ▶ Node degree in networks: # friends, # hyperlinks, etc.
- ▶ # citations for articles, court decisions, etc.

$$P(k) \sim ck^{-\gamma}$$

where $k_{\min} \leq k \leq k_{\max}$

- ▶ Obvious fail for $k = 0$.
- ▶ Again, typically a description of distribution's tail.

Power-Law Size Distributions

- Our Intuition
- Definition
- Examples
- Wild vs. Mild
- CCDFs
- Zipf's law
- Zipf ↔ CCDF
- References

$$P(x) \sim x^{-\delta}$$

The sizes of many systems' elements appear to obey an inverse power-law size distribution:

$$P(\text{size} = x) \sim cx^{-\gamma}$$

where $0 < x_{\min} < x < x_{\max}$ and $\gamma > 1$.

- ▶ Exciting class exercise: sketch this function.
- ▶ x_{\min} = lower cutoff, x_{\max} = upper cutoff
- ▶ Negative linear relationship in log-log space:

$$\log_{10} P(x) = \log_{10} c - \gamma \log_{10} x$$

- ▶ We use base 10 because we are good people.
- ▶ power-law decays in probability: The Statistics of Surprise.

The statistics of surprise:

From: “Quake Moves Japan Closer to U.S. and Alters Earth's Spin” (田) by Kenneth Chang, March 13, 2011, NYT:

“What is perhaps most surprising about the Japan earthquake is how misleading history can be. In the past 300 years, no earthquake nearly that large—nothing larger than magnitude eight—had struck in the Japan subduction zone. That, in turn, led to assumptions about how large a tsunami might strike the coast.”

“It did them a giant disservice,” said Dr. Stein of the geological survey. That is not the first time that the earthquake potential of a fault has been underestimated. Most geophysicists did not think the Sumatra fault could generate a magnitude 9.1 earthquake, ...”

And in general...

Moments:

- ▶ All moments depend only on cutoffs.
- ▶ No internal scale that dominates/matters.
- ▶ Compare to a Gaussian, exponential, etc.

For many real size distributions: $2 < \gamma < 3$

- ▶ mean is finite (depends on lower cutoff)
- ▶ $\sigma^2 =$ variance is 'infinite' (depends on upper cutoff)
- ▶ Width of distribution is 'infinite'
- ▶ If $\gamma > 3$, distribution is less terrifying and may be easily confused with other kinds of distributions.

Moments

Standard deviation is a mathematical convenience:

- ▶ Variance is nice analytically...
- ▶ Another measure of distribution width:

$$\text{Mean average deviation (MAD)} = \langle |x - \langle x \rangle| \rangle$$

- ▶ For a pure power law with $2 < \gamma < 3$:

$$\langle |x - \langle x \rangle| \rangle \text{ is finite.}$$

- ▶ But MAD is mildly unpleasant analytically...
- ▶ We still speak of infinite 'width' if $\gamma < 3$.

Devilish power-law size distribution details:

Exhibit A:

- ▶ Given $P(x) = cx^{-\gamma}$ with $0 < x_{\min} < x < x_{\max}$, the mean is ($\gamma \neq 2$):

$$\langle x \rangle = \frac{c}{2-\gamma} \left(x_{\max}^{2-\gamma} - x_{\min}^{2-\gamma} \right).$$

- ▶ Mean 'blows up' with upper cutoff if $\gamma < 2$.
- ▶ Mean depends on lower cutoff if $\gamma > 2$.
- ▶ $\gamma < 2$: Typical sample is large.
- ▶ $\gamma > 2$: Typical sample is small.

How sample sizes grow...

Given $P(x) \sim cx^{-\gamma}$:

- ▶ We can show that after n samples, we expect the largest sample to be

$$x_1 \gtrsim c'n^{1/(\gamma-1)}$$

- ▶ Sampling from a finite-variance distribution gives a much slower growth with n .
- ▶ e.g., for $P(x) = \lambda e^{-\lambda x}$, we find

$$x_1 \gtrsim \frac{1}{\lambda} \ln n.$$

Insert question from assignment 2 (田)

Power-Law Size Distributions

$$P(x) \sim x^{-\delta}$$

30 of 43

Complementary Cumulative Distribution Function:

CCDF:

$$\begin{aligned}
 P_{\geq}(x) &= P(x' \geq x) = 1 - P(x' < x) \\
 &= \int_{x'=x}^{\infty} P(x') dx' \\
 &\propto \int_{x'=x}^{\infty} (x')^{-\gamma} dx' \\
 &= \frac{1}{-\gamma + 1} (x')^{-\gamma+1} \Big|_{x'=x}^{\infty} \\
 &\propto x^{-\gamma+1}
 \end{aligned}$$

$$P(x) \sim x^{-\delta}$$

Zipfian rank-frequency plots

George Kingsley Zipf:

- ▶ Noted various rank distributions have power-law tails, often with exponent -1 (word frequency, city sizes...)
- ▶ Zipf's 1949 Magnum Opus (田):

- ▶ We'll study Zipf's law in depth...

$$P(x) \sim x^{-\delta}$$

Complementary Cumulative Distribution Function:

CCDF:

$$P_{\geq}(x) \propto x^{-\gamma+1}$$

- ▶ Use when tail of P follows a power law.
- ▶ Increases exponent by one.
- ▶ Useful in cleaning up data.

$$P(x) \sim x^{-\delta}$$

Zipfian rank-frequency plots

Zipf's way:

- ▶ Given a collection of entities, rank them by size, largest to smallest.
- ▶ x_r = the size of the r th ranked entity.
- ▶ $r = 1$ corresponds to the largest size.
- ▶ Example: x_1 could be the frequency of occurrence of the most common word in a text.
- ▶ Zipf's observation:

$$x_r \propto r^{-\alpha}$$

$$P(x) \sim x^{-\delta}$$

PDF:

CCDF:

$$P(x) \sim x^{-\delta}$$

Size distributions:

Brown Corpus (1,015,945 words):

CCDF:

Zipf:

- ▶ The, of, and, to, a, ... = 'objects'
- ▶ 'Size' = word frequency
- ▶ **Beep:** (Important) CCDF and Zipf plots are related...

$$P(x) \sim x^{-\delta}$$

Complementary Cumulative Distribution Function:

- ▶ Discrete variables:

$$\begin{aligned}
 P_{\geq}(k) &= P(k' \geq k) \\
 &= \sum_{k'=k}^{\infty} P(k) \\
 &\propto k^{-\gamma+1}
 \end{aligned}$$

- ▶ Use integrals to approximate sums.

Size distributions:

Brown Corpus (1,015,945 words):

CCDF:

Zipf:

- ▶ The, of, and, to, a, ... = 'objects'
- ▶ 'Size' = word frequency
- ▶ **Beep:** (Important) CCDF and Zipf plots are related...

Observe:

- ▶ $NP_{\geq}(x)$ = the number of objects with size at least x where N = total number of objects.
- ▶ If an object has size x_r , then $NP_{\geq}(x_r)$ is its rank r .
- ▶ So

$$x_r \propto r^{-\alpha} = (NP_{\geq}(x_r))^{-\alpha}$$

$$\propto x_r^{(-\gamma+1)(-\alpha)} \text{ since } P_{\geq}(x) \sim x^{-\gamma+1}.$$

We therefore have $1 = (-\gamma + 1)(-\alpha)$ or:

$$\alpha = \frac{1}{\gamma - 1}$$

- ▶ A rank distribution exponent of $\alpha = 1$ corresponds to a size distribution exponent $\gamma = 2$.

The Don. (田)

Extreme deviations in test cricket:

- ▶ Don Bradman's batting average (田) = 166% next best.
- ▶ That's pretty solid.
- ▶ Later in the course: Understanding success—is the Mona Lisa like Don Bradman?
