Scaling—a Plenitude of Power Laws
Principles of Complex Systems
Course 300, Fall, 2008

Definitions

General observation:

Systems (complex or not) that cross many spatial and temporal scales often exhibit some form of scaling.
Outline

All about scaling:

- Definitions.
- Examples.
- How to measure your power-law relationship.
- Mechanisms giving rise to your power-laws.
A power law relates two variables $x$ and $y$ as follows:

$$y = cx^\alpha$$

- $\alpha$ is the scaling exponent (or just exponent)
- $(\alpha$ can be any number in principle but we will find various restrictions.)
- $c$ is the prefactor (which can be important!)
Definitions

- The prefactor $c$ must balance dimensions.
- e.g., length $\ell$ and volume $v$ of common nails are related as:
  $$\ell = cv^{1/4}$$
- Using $[\cdot]$ to indicate dimension, then
  $$[c] = [\ell]/[V^{1/4}] = L/L^{3/4} = L^{1/4}.$$
Looking at data

- Power-law relationships are linear in log-log space:
  \[ y = cx^\alpha \]
  \[ \Rightarrow \log_b y = \alpha \log_b x + \log_b c \]
  with slope equal to \( \alpha \), the scaling exponent.

- Much searching for straight lines on log-log or double-logarithmic plots.

- Good practice: Always, always, always use base 10.

- Talk only about orders of magnitude (powers of 10).
A beautiful, heart-warming example: $\alpha \approx 1.23$

gray matter: ‘computing elements’

white matter: ‘wiring’

from Zhang & Sejnowski, PNAS (2000)
Why is $\alpha \simeq 1.23$?

Quantities (following Zhang and Sejnowski):

- $G =$ Volume of gray matter (cortex/processors)
- $W =$ Volume of white matter (wiring)
- $T =$ Cortical thickness (wiring)
- $S =$ Cortical surface area
- $L =$ Average length of white matter fibers
- $p =$ density of axons on white matter/cortex interface

A rough understanding:

- $G \sim ST$ (convolutions are okay)
- $W \sim \frac{1}{2}pSL$
- $G \sim L^3$ ← this is a little sketchy...
- Eliminate $S$ and $L$ to find $W \propto \frac{G^{4/3}}{T}$
Why is $\alpha \simeq 1.23$?

A rough understanding:

- We are here: $W \propto G^{4/3} / T$
- Observe weak scaling $T \propto G^{0.10 \pm 0.02}$.
- (Implies $S \propto G^{0.9} \rightarrow$ convolutions fill space.)
- $\Rightarrow W \propto G^{4/3} / T \propto G^{1.23 \pm 0.02}$
Why is $\alpha \approx 1.23$?

**Trickiness:**

- With $V = G + W$, some power laws must be approximations.
- Measuring exponents is a hairy business...
Good scaling:

General rules of thumb:

- **High quality**: scaling persists over three or more orders of magnitude for each variable.

- **Medium quality**: scaling persists over three or more orders of magnitude for only one variable and at least one for the other.

- **Very dubious**: scaling ‘persists’ over less than an order of magnitude for both variables.
Unconvincing scaling:

Average walking speed as a function of city population:

Two problems:
1. use of natural log, and
2. minute variation in dependent variable.

from Bettencourt et al. (2007) \[3\]; otherwise very interesting!
Definitions

Power laws are the signature of scale invariance:

Scale invariant ‘objects’ look the ‘same’ when they are appropriately rescaled.

- **Objects** = geometric shapes, time series, functions, relationships, distributions,...
- ‘Same’ might be ‘statistically the same’
- To rescale means to change the units of measurement for the relevant variables
Scale invariance

Our friend $y = cx^α$:

- If we rescale $x$ as $x = rx'$ and $y$ as $y = r^α y'$,
- then

$$r^α y' = c(rx')^α$$

- $\Rightarrow y' = cr^α x'^{α} r^{-α}$
- $\Rightarrow y' = c x'^{α}$
Scale invariance

Compare with $y = ce^{-\lambda x}$:

- If we rescale $x$ as $x = rx'$, then
  $$y = ce^{-\lambda rx'}$$

- Original form cannot be recovered.
- $\Rightarrow$ scale matters for the exponential.
Scale invariance

More on $y = ce^{-\lambda x}$:

- Say $x_0 = 1/\lambda$ is the characteristic scale.
- For $x \gg x_0$, $y$ is small, while for $x \ll x_0$, $y$ is large.
- ⇒ More on this later with size distributions.
Allometry: 

[refers to] differential growth rates of the parts of a living organism’s body part or process.
Definitions:

Isometry: dimensions scale linearly with each other.

Allometry: dimensions scale nonlinearly.
Definitions

Isometry versus Allometry:

- Isometry = ‘same measure’
- Allometry = ‘other measure’

Confusingly, we use allometric scaling to refer to both:

1. nonlinear scaling (e.g., $x \propto y^{1/3}$)
2. and the relative scaling of different measures (e.g., resting heart rate as a function of body size)
A wonderful treatise on scaling:

Bonner and McMahon, 1983[6]
The biggest living things (left). All the organisms are drawn to the same scale. 1, The largest flying bird (albatross); 2, the largest known animal (the blue whale), 3, the largest extinct land mammal (*Baluchitherium*) with a human figure shown for scale; 4, the tallest living land animal (giraffe); 5, *Tyrannosaurus*; 6, *Diplodocus*; 7, one of the largest flying reptiles (*Pteranodon*); 8, the largest extinct snake; 9, the length of the largest tapeworm found in man; 10, the largest living reptile (West African crocodile); 11, the largest extinct lizard; 12, the largest extinct bird (*Aepyornis*); 13, the largest jellyfish (*Cyanea*); 14, the largest living lizard (Komodo dragon); 15, sheep; 16, the largest bivalve mollusc (*Tridacna*); 17, the largest fish (whale shark); 18, horse; 19, the largest crustacean (Japanese spider crab); 20, the largest sea scorpion (*Eurypterid*); 21, large tarpon; 22, the largest lobster; 23, the largest mollusc (deep-water squid, *Architeuthis*); 24, ostrich; 25, the lower 105 feet of the largest organism (giant sequoia), with a 100-foot larch superposed.

The many scales of life:

Medium-sized creatures (above). 1, Dog; 2, common herring; 3, the largest egg (Aepyornis); 4, song thrush with egg; 5, the smallest bird (hummingbird) with egg; 6, queen bee; 7, common cockroach; 8, the largest stick insect; 9, the largest polyp (Branchiocerianthus); 10, the smallest mammal (flying shrew); 11, the smallest vertebrate (a tropical frog); 12, the largest frog (goliath frog); 13, common grass frog; 14, house mouse; 15, the largest land snail (Achatina) with egg; 16, common snail; 17, the largest beetle (goliath beetle); 18, human hand; 19, the largest starfish (Luidia); 20, the largest free-moving protozoan (an extinct nummulite).
The many scales of life:

p. 3, Bonner and McMahon[6]
Small, “naked-eye” creatures (lower left). 1, One of the smallest fishes (Trimmatom nanus); 2, common brown hydra, expanded; 3, housefly; 4, medium-sized ant; 5, the smallest vertebrate (a tropical frog, the same as the one numbered 11 in the figure above); 6, flea (Xenopsylla cheopis); 7, the smallest land snail; 8, common water flea (Daphnia).

The smallest “naked-eye” creatures and some large microscopic animals and cells (below right). 1, Vorticella, a ciliate; 2, the largest ciliate protozoan (Bursaria); 3, the smallest many-celled animal (a rotifer); 4, smallest flying insect (Elaphis); 5, another ciliate (Paramecium); 6, cheese mite; 7, human sperm; 8, human ovum; 9, dysentery amoeba; 10, human liver cell; 11, the foreleg of the flea (numbered 6 in the figure to the left).

The many scales of life:

p. 3, Bonner and McMahon[6]
Size range and cell differentiation:

<table>
<thead>

The graph shows the relationship between the number of cell types and the approximate number of cells for various organisms. The x-axis represents the number of cell types, and the y-axis represents the volume in cm³.
Non-uniform growth:

p. 32, Bonner and McMahon[6]
Non-uniform growth—arm length versus height:

Good example of a break in scaling:

A crossover in scaling occurs around a height of 1 metre.

p. 32, Bonner and McMahon[6]
Weightlifting: $M_{\text{worldrecord}} \propto M_{\text{lifter}}^{2/3}$

Idea: Power $\sim$ cross-sectional area of isometric lifters.

p. 53, Bonner and McMahon [6]
Titanotherae horns: $L_{\text{horn}} \sim L_{\text{skull}}^4$

p. 36, Bonner and McMahon [6]
The allometry of nails:

- Diameter $\propto \text{Mass}^{3/8}$
- Length $\propto \text{Mass}^{1/4}$
- Diameter $\propto \text{Length}^{2/3}$

The allometry of nails:

A buckling instability?:

- Physics/Engineering result: Columns buckle under a load which depends on $d^4/\ell^2$.
- To drive nails in, resistive force $\propto$ nail circumference $= \pi d$.
- Match forces independent of nail size: $d^4/\ell^2 \propto d$.
- Leads to $d \propto \ell^{2/3}$. 
Rowing: Speed $\propto$ \((\text{number of rowers})^{1/9}\)

Scaling in Cities:

Intriguing findings:

- Global supply costs scale sublinearly with $N (\beta < 1)$.
  - Returns to scale for infrastructure.
- Total individual costs scale linearly with $N (\beta = 1)$
  - Individuals consume similar amounts independent of city size.
- Social quantities scale superlinearly with $N (\beta > 1)$
  - Creativity (# patents), wealth, disease, crime, ...

Density doesn’t seem to matter...

- Surprising given that across the world, we observe two orders of magnitude variation in area covered by agglomerations of fixed populations.
Allegedly (data is messy):

- On islands: $\beta \approx 1/4$.
- On continuous land: $\beta \approx 1/8$. 
A focus:

- How much energy do organisms need to live?
- And how does this scale with organismal size?
Animal power

Fundamental biological and ecological constraint:

\[ P = c M^\alpha \]

\( P = \text{basal metabolic rate} \)
\( M = \text{organismal body mass} \)
$P = c M^\alpha$

Prefactor $c$ depends on **body plan** and **body temperature**:

- **Birds**: 39–41 °C
- **Eutherian Mammals**: 36–38 °C
- **Marsupials**: 34–36 °C
- **Monotremes**: 30–31 °C
What one might expect:

\[ \alpha = \frac{2}{3} \] because . . .

- Dimensional analysis suggests an energy balance surface law:

\[ P \propto S \propto V^{2/3} \propto M^{2/3} \]

- Lognormal fluctuations: Gaussian fluctuations in log \( P \) around log \( cM^\alpha \).

- Stefan-Boltzmann relation for radiated energy:

\[ \frac{dE}{dt} = \sigma \varepsilon ST^4 \]
The prevailing belief of the church of quarterology

\[ \alpha = \frac{3}{4} \]

\[ P \propto M^{3/4} \]

Huh?
Related putative scalings:

- number of capillaries $\propto M^{3/4}$
- time to reproductive maturity $\propto M^{1/4}$
- heart rate $\propto M^{-1/4}$
- cross-sectional area of aorta $\propto M^{3/4}$
- population density $\propto M^{-3/4}$
The great ‘law’ of heartbeats:

Assuming:

- Average lifespan $\propto M^\beta$
- Average heart rate $\propto M^{-\beta}$
- Irrelevant but perhaps $\beta = 1/4$.

Then:

- Average number of heart beats in a lifespan $\propto (\text{Average lifespan}) \times (\text{Average heart rate})$
  $\propto M^{\beta - \beta}$
  $\propto M^0$

- Number of heartbeats per life time is independent of organism size!

- $\approx 1.5$ billion....
1840’s: Sarrus and Rameaux\textsuperscript{[22]} first suggested $\alpha = 2/3$. 

\[\text{Scaling} \quad \text{Scaling-at-large} \quad \text{Allometry} \quad \text{Definitions} \quad \text{Examples} \quad \text{History: Metabolism} \quad \text{Measuring exponents} \quad \text{History: River networks} \quad \text{Earlier theories} \quad \text{Geometric argument} \quad \text{Blood networks} \quad \text{River networks} \quad \text{Conclusion} \quad \text{References} \]
1883: Rubner\textsuperscript{[21]} found $\alpha \approx 2/3$. 
1930’s: Brody, Benedict study mammals.\cite{7}
Found $\alpha \simeq 0.73$ (standard).
1932: Kleiber analyzed 13 mammals. \[16\]
Found $\alpha = 0.76$ and suggested $\alpha = 3/4$. 

![Image of scale]

Some data on metabolic rates

Heusner’s data (1991) \[15\]

- 391 Mammals
- blue line: 2/3
- red line: 3/4.

\( B = 0.026 M^{0.668} \)
Some data on metabolic rates

\[ B = 0.041 \, M^{0.664} \]

- Bennett and Harvey’s data (1987) \[^2\]
- 398 birds
- blue line: 2/3
- red line: 3/4.
- \((B = P)\)

Passerine vs. non-passerine...
Important:

- Ordinary Least Squares (OLS) Linear regression is only appropriate for analyzing a dataset \{ (x_i, y_i) \} when we know the $x_i$ are measured without error.
- Here we assume that measurements of mass $M$ have less error than measurements of metabolic rate $B$.
- Linear regression assumes Gaussian errors.
Measuring exponents

More on regression:
If (a) we don’t know what the errors of either variable are, or (b) no variable can be considered independent, then we need to use Standardized Major Axis Linear Regression. aka Reduced Major Axis = RMA.
Measuring exponents

For Standardized Major Axis Linear Regression:

\[ \text{slope}_{SMA} = \frac{\text{standard deviation of } y \text{ data}}{\text{standard deviation of } x \text{ data}} \]

Very simple!
Measuring exponents

Relationship to ordinary least squares regression is simple:

\[
\text{slope}_{\text{SMA}} = r^{-1} \times \text{slope}_{\text{OLS } y \text{ on } x} = r \times \text{slope}_{\text{OLS } x \text{ on } y}
\]

where \( r = \) standard correlation coefficient:

\[
r = \frac{\sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n} (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^{n} (y_i - \bar{y})^2}}
\]

Hypothesis testing

Test to see if $\alpha'$ is consistent with our data $\{(M_i, B_i)\}$:

$$H_0 : \alpha = \alpha' \text{ and } H_1 : \alpha \neq \alpha'.$$

- Assume each $B_i$ (now a random variable) is normally distributed about $\alpha' \log_{10} M_i + \log_{10} c$.
- Follows that the measured $\alpha$ for one realization obeys a $t$ distribution with $N - 2$ degrees of freedom.
- Calculate a $p$-value: probability that the measured $\alpha$ is as least as different to our hypothesized $\alpha'$ as we observe.

(see, for example, DeGroot and Scherish, “Probability and Statistics”[8])

Fluctuations—Kolmogorov-Smirnov test

\[ P(B | M) = \frac{1}{M^{2/3}} f(B/M^{2/3}) \]
Analysis of residuals

1. Presume an exponent of your choice: 2/3 or 3/4.
2. Fit the prefactor ($\log_{10} c$) and then examine the residuals:

   $$ r_i = \log_{10} B_i - (\alpha' \log_{10} M_i - \log_{10} c). $$

3. $H_0$: residuals are uncorrelated
   $H_1$: residuals are correlated.
4. Measure the correlations in the residuals and compute a $p$-value.
Analysis of residuals

We use the spiffing **Spearman Rank-Order Correlation Coefficient**.

**Basic idea:**

- Given \( \{(x_i, y_i)\} \), rank the \( \{x_i\} \) and \( \{y_i\} \) separately from smallest to largest. Call these ranks \( R_i \) and \( S_i \).
- Now calculate correlation coefficient for ranks, \( r_s \):

\[
r_s = \frac{\sum_{i=1}^{n}(R_i - \bar{R})(S_i - \bar{S})}{\sqrt{\sum_{i=1}^{n}(R_i - \bar{R})^2} \sqrt{\sum_{i=1}^{n}(S_i - \bar{S})^2}}
\]

- Perfect correlation: \( x_i \)'s and \( y_i \)'s both increase monotonically.
We assume all rank orderings are equally likely:

- $r_s$ is distributed according to a Student’s distribution with $N - 2$ degrees of freedom.
- Excellent feature: Non-parametric—real distribution of $x$’s and $y$’s doesn’t matter.
- Bonus: works for non-linear monotonic relationships as well.
- See “Numerical Recipes in C/Fortran” which contains many good things. [20]
Analysis of residuals—mammals

(a) $M < 3.2$ kg, (b) $M < 10$ kg, (c) $M < 32$ kg, (d) all mammals.
Analysis of residuals—birds

(a) $M < .1$ kg, (b) $M < 1$ kg, (c) $M < 10$ kg, (d) all birds.
Basic basin quantities: \( a, l, L_{\parallel}, L_{\perp} \):

- \( a = \) drainage basin area
- \( l = \) length of longest (main) stream
- \( L = L_{\parallel} = \) longitudinal length of basin
River networks

- 1957: J. T. Hack\textsuperscript{[12]}
  “Studies of Longitudinal Stream Profiles in Virginia and Maryland”
  \[ \ell \sim a^h \]
  \[ h \sim 0.6 \]

- Anomalous scaling: we would expect \( h = 1/2 \ldots \)
- Subsequent studies: \( 0.5 \lesssim h \lesssim 0.6 \)
- Another quest to find universality/god...
- A catch: studies done on small scales.
Large-scale networks

(1992) Montgomery and Dietrich\textsuperscript{[19]}:

- **Composite data set**: includes everything from unchanneled valleys up to world’s largest rivers.
- **Estimated fit**:

\[ L \sim 1.78a^{0.49} \]

- **Mixture of basin and main stream lengths.**
World’s largest rivers only:

- Data from Leopold (1994)\(^{[17, 9]}\)
- Estimate of Hack exponent: \( h = 0.50 \pm 0.06 \)
Earlier theories

Building on the surface area idea...

- Blum (1977)\textsuperscript{[5]} speculates on four-dimensional biology:

\[ P \propto M^{(d-1)/d} \]

- \( d = 3 \) gives \( \alpha = 2/3 \)
- \( d = 4 \) gives \( \alpha = 3/4 \)
- So we need another dimension...
- Obviously, a bit silly.
Earlier theories

Building on the surface area idea:

- McMahon (70’s, 80’s): Elastic Similarity \^[18, 6\]
- Idea is that organismal shapes scale allometrically with 1/4 powers (like nails and trees…)
- Appears to be true for ungulate legs.
- Metabolism and shape never properly connected.
Nutrient delivering networks:

- 1960’s: Rashevsky considers blood networks and finds a 2/3 scaling.
Nutrient delivering networks:

West et al.’s assumptions:

- hierarchical network
- capillaries (delivery units) invariant
- network impedance is minimized via evolution

Claims:

- $P \propto M^{3/4}$
- networks are fractal
- quarter powers everywhere
Impedance measures:

Poiseuille flow (outer branches):

\[ Z = \frac{8\mu}{\pi} \sum_{k=0}^{N} \frac{\ell_k}{r_k^4 N_k} \]

Pulsatile flow (main branches):

\[ Z \propto \sum_{k=0}^{N} \frac{h_k^{1/2}}{r_k^{5/2} N_k} \]
Not so fast . . .

Actually, model shows:

- $P \propto M^{3/4}$ does not follow for pulsatile flow
- networks are not necessarily fractal.

Do find:

- Murray’s cube law (1927) for outer branches:
  \[ r_0^3 = r_1^3 + r_2^3 \]
- Impedance is distributed evenly.
- Can still assume networks are fractal.
Connecting network structure to $\alpha$

1. Ratios of network parameters:

$$R_n = \frac{n_{k+1}}{n_k}, \quad R_\ell = \frac{\ell_{k+1}}{\ell_k}, \quad R_r = \frac{r_{k+1}}{r_k}$$

2. Number of capillaries $\propto P \propto M^\alpha$.

$$\Rightarrow \quad \alpha = -\frac{\ln R_n}{\ln R_r^2 R_\ell}$$

(also problematic due to prefactor issues)

Soldiering on, assert:

- area-preservingness: $R_r = R_n^{-1/2}$
- space-fillingness: $R_\ell = R_n^{-1/3}$

$$\Rightarrow \quad \alpha = 3/4$$

Simple supply networks

- Flow rate argument
- Ignore impedance
- Very general attempt to find most efficient transportation networks

References

Simple supply networks

- Banavar et al. find ‘most efficient’ networks with
  \[ P \propto M^{d/(d+1)} \]

- ... but also find
  \[ V_{\text{network}} \propto M^{(d+1)/d} \]

- \( d = 3 \):
  \[ V_{\text{blood}} \propto M^{4/3} \]

- Consider a 3 g shrew with \( V_{\text{blood}} = 0.1 V_{\text{body}} \)
- \( \Rightarrow \) 3000 kg elephant with \( V_{\text{blood}} = 10 V_{\text{body}} \)
- Such a pachyderm would be rather miserable.
Geometric argument

- Consider one source supplying many sinks in a $d$-dim. volume in a $D$-dim. ambient space.
- Assume sinks are invariant.
- Assume $\rho = \rho(V)$.
- Assume some cap on flow speed of material.
- See network as a bundle of virtual vessels:

$$Q: \text{how does the number of sustainable sinks } N_{\text{sinks}} \text{ scale with volume } V \text{ for the most efficient network design?}$$

- Or: what is the highest $\alpha$ for $N_{\text{sinks}} \propto V^\alpha$?
Geometric argument

- Allometrically growing regions:

- Have $d$ length scales which scale as

  \[ L_i \propto V^{\gamma_i} \text{ where } \gamma_1 + \gamma_2 + \ldots + \gamma_d = 1. \]

- For \textit{isometric} growth, $\gamma_i = 1/d$.
- For \textit{allometric} growth, we must have at least two of the \{\gamma_i\} being different.
Geometric argument

- Best and worst configurations (Banavar et al.)

- Rather obviously:
  \[
  \min V_{\text{net}} \propto \sum \text{distances from source to sinks.}
  \]
Minimal network volume:

Real supply networks are close to optimal:

Figure 1. (a) Commuter rail network in the Boston area. The arrow marks the assumed root of the network. (b) Star graph. (c) Minimum spanning tree. (d) The model of equation (3) applied to the same set of stations.

Minimal network volume:

Approximate network volume by integral over region:

\[
\min V_{\text{net}} \propto \int_{\Omega_{d,D}(V)} \rho \|\vec{x}\| \, d\vec{x}
\]

\[
\rightarrow \rho V^{1+\gamma_{\text{max}}} \int_{\Omega_{d,D}(c)} (c_1^2 u_1^2 + \ldots + c_k^2 u_k^2)^{1/2} \, d\vec{u}
\]

\[
\propto \rho V^{1+\gamma_{\text{max}}}
\]
Geometric argument

- General result:

\[
\min V_{\text{net}} \propto \rho V^{1+\gamma_{\text{max}}}
\]

- If scaling is isometric, we have \( \gamma_{\text{max}} = 1/d \):

\[
\min V_{\text{net/iso}} \propto \rho V^{1+1/d} = \rho V^{(d+1)/d}
\]

- If scaling is allometric, we have \( \gamma_{\text{max}} = \gamma_{\text{allo}} > 1/d \):

\[
\min V_{\text{net/allo}} \propto \rho V^{1+\gamma_{\text{allo}}}
\]

- Isometrically growing volumes require less network volume than allometrically growing volumes:

\[
\frac{\min V_{\text{net/iso}}}{\min V_{\text{net/allo}}} \rightarrow 0 \text{ as } V \rightarrow \infty
\]
Blood networks

- **Material costly** ⇒ expect lower optimal bound of $V_{\text{net}} \propto \rho V^{(d+1)/d}$ to be followed closely.
- For cardiovascular networks, $d = D = 3$.
- Blood volume scales linearly with blood volume\(^{[23]}\), $V_{\text{net}} \propto V$.
- Sink density must decrease as volume increases: $ho \propto V^{-1/d}$.
- Density of suppliable sinks decreases with organism size.
Blood networks

Then $P$, the rate of overall energy use in $\Omega$, can at most scale with volume as

$$P \propto \rho V \propto \rho M \propto M^{(d-1)/d}$$

For $d = 3$ dimensional organisms, we have

$$P \propto M^{2/3}$$
Recap:

- The exponent $\alpha = 2/3$ works for all birds and mammals up to 10–30 kg
- For mammals $> 10$–30 kg, maybe we have a new scaling regime
- Economos: limb length break in scaling around 20 kg
- White and Seymour, 2005: unhappy with large herbivore measurements. Find $\alpha \simeq 0.686 \pm 0.014$
Prefactor:

Stefan-Boltzmann law:

\[ \frac{dE}{dt} = \sigma ST^4 \]

where \( S \) is surface and \( T \) is temperature.

- Very rough estimate of prefactor based on scaling of normal mammalian body temperature and surface area \( S \):
  \[ B \simeq 10^5 M^{2/3} \text{erg/sec}. \]

- Measured for \( M \leq 10 \) kg:
  \[ B = 2.57 \times 10^5 M^{2/3} \text{erg/sec}. \]
River networks

- View river networks as collection networks.
- Many sources and one sink.
- Assume $\rho$ is constant over time:

$$V_{\text{net}} \propto \rho V^{(d+1)/d} = \text{constant} \times V^{3/2}$$

- Network volume grows faster than basin ‘volume’ (really area).
- It’s all okay:
  Landscapes are $d=2$ surfaces living in $D=3$ dimension.
- Streams can grow not just in width but in depth...
Hack’s law

- Volume of water in river network can be calculated by adding up basin areas
- Flows sum in such a way that

\[ V_{\text{net}} = \sum_{\text{all pixels}} a_{\text{pixel } i} \]

- Hack’s law again:

\[ \ell \sim a^h \]

- Can argue

\[ V_{\text{net}} \propto V_{\text{basin}}^{1+h} = a_{\text{basin}}^{1+h} \]

where \( h \) is Hack’s exponent.
- \( \therefore \) minimal volume calculations gives

\[ h = 1/2 \]
Real data:

- Banavar et al.'s approach \[1\] is okay because $\rho$ really is constant.
- The irony: shows optimal basins are isometric.
- Optimal Hack’s law: $a \sim \ell^h$ with $h = 1/2$
- (Zzzzz)

From Banavar et al. (1999) \[1\]
Even better—prefactors match up:

![Graph showing log10 water volume (m$^3$) vs. log10 area (m$^2$) for Amazon, Mississippi, Congo, and Nile rivers.](image)

- Amazon
- Mississippi
- Congo
- Nile

\[
\log_{10} \text{area } a \ [\text{m}^2]
\]
\[
\log_{10} \text{water volume } V \ [\text{m}^3]
\]
Conclusion

- Supply network story consistent with dimensional analysis.
- Isometrically growing regions can be more efficiently supplied than allometrically growing ones.
- Ambient and region dimensions matter ($D = d$ versus $D > d$).
- Deviations from optimal scaling suggest inefficiency (e.g., gravity for organisms, geological boundaries).
- Actual details of branching networks not that important.
- Exact nature of self-similarity varies.
