What's
The
Story?

Principles of Complex Systems, CSYS/MATH 300
University of Vermont, Fall 2017

Assignment 4 • code name: Only two hours from the beach

Dispersed: Friday, September 22, 2017.

Due: By 11:59 pm, Friday, September 29, 2017.

Some useful reminders:

Deliverator: Peter Dodds

Office: Farrell Hall, second floor, Trinity Campus

E-mail: peter.dodds+pocs@uvm.edu

Office hours: 1:15 pm to 2:30 pm on Tuesday, 1:15 pm to 4:45 pm Thursday

Course website: <http://www.uvm.edu/pdodds/teaching/courses/2017-08UVM-300>

Bonus course notes: <http://www.uvm.edu/pdodds/teaching/courses/2017-08UVM-300/docs/dewhurst-pocs-notes.pdf>

All parts are worth 3 points unless marked otherwise. Please show all your workingses clearly and list the names of others with whom you collaborated.

Please obey the basic life rule: Never use Excel.

Graduate students are requested to use \LaTeX (or related \TeX variant).

Email submission: PDF only! Please name your file as follows (where the number is to be padded by a 0 if less than 10 and names are all lowercase):

CSYS300assignment%02d\$firstname-\$lastname.pdf as in

CSYS300assignment06michael-palin.pdf

Please submit your project's current draft in pdf format via email. Please use this file name format (all lowercase after CSYS):

CSYS300project-\$firstname-\$lastname-YYYY-MM-DD.pdf as in

CSYS300project-lisa-simpson-1989-12-17.pdf where the date is the date of submission (and not, say, your birthdate).

1. Code up Simon's rich-gets-richer model.

Show Zipf distributions for $\rho = 0.10, 0.01, \text{ and } 0.001$. and perform regressions to test $\alpha = 1 - \rho$.

Run the simulation for long enough to produce decent scaling laws (recall: three orders of magnitude is good).

Averaging over simulations will produce cleaner results so try 10 and then, if possible, 100.

Note the first mover advantage.

2. (3 + 3 + 3 points) For Herbert Simon's model of what we've called Random Competitive Replication, we found in class that the normalized number of groups in the long time limit, n_k , satisfies the following difference equation:

$$\frac{n_k}{n_{k-1}} = \frac{(k-1)(1-\rho)}{1+(1-\rho)k} \quad (1)$$

where $k \geq 2$. The model parameter ρ is the probability that a newly arriving node forms a group of its own (or is a novel word, starts a new city, has a unique flavor, etc.). For $k = 1$, we have instead

$$n_1 = \rho - (1-\rho)n_1 \quad (2)$$

which directly gives us n_1 in terms of ρ .

- (a) Derive the exact solution for n_k in terms of gamma functions and ultimately the beta function.
- (b) From this exact form, determine the large k behavior for n_k ($\sim k^{-\gamma}$) and identify the exponent γ in terms of ρ . You are welcome to use the fact that $B(x, y) \sim x^{-y}$ for large x and fixed y (use Stirling's approximation or possibly Wikipedia).

Note: Simon's own calculation is slightly awry. The end result is good however.

Hint—Setting up Simon's model:

<http://www.youtube.com/watch?v=0TzI5J5W1K0>

The hint's output including the bits not in the video:

$$\frac{n_k}{n_{k-1}} = \frac{(k-1)(1-\rho)}{1+(1-\rho)k}$$

$$n_k = \left[\frac{(k-1)(1-\rho)}{1+(1-\rho)k} \right] \left[\frac{(k-2)(1-\rho)}{1+(1-\rho)(k-1)} \right] n_{k-2} \dots \left[\frac{(k-3)(1-\rho)}{1+(1-\rho)(k-2)} \right] n_{k-3} \dots \left[\frac{(2)(1-\rho)}{1+(1-\rho)2} \right] n_1$$

$\Gamma(k) = (k-1)!$

$$\Gamma(x+1) = x \Gamma(x)$$

$x = n+1 \quad \Gamma(n+1) = n \Gamma(n) = \dots = n! \quad \Gamma(1) = 1$

example $0 < z < 1$

$$(1+zk)(1+z(k-1)) \dots (1+z)$$

$$= z^k \left(\frac{1}{z} + k \right) \left(\frac{1}{z} + k - 1 \right) \dots \left(\frac{1}{z} + 1 \right) = z^k \frac{\left(\frac{1}{z} + k \right) \left(\frac{1}{z} + k - 1 \right) \dots}{\frac{1}{z} \cdot \left(\frac{1}{z} - 1 \right) \left(\frac{1}{z} - 2 \right) \dots}$$

differ by 1

$$= z^k \frac{\Gamma\left(\frac{1}{z} + k + 1\right)}{\Gamma\left(\frac{1}{z} + 1\right)}$$

3. What happens to γ in the limits $\rho \rightarrow 0$ and $\rho \rightarrow 1$? Explain in a sentence or two what's going on in these cases and how the specific limiting value of γ makes sense.

4. (6 + 3 + 3 points)

In Simon's original model, the expected total number of distinct groups at time t is ρt . Recall that each group is made up of elements of a particular flavor.

In class, we derived the fraction of groups containing only 1 element, finding

$$n_1^{(g)} = \frac{N_1(t)}{\rho t} = \frac{1}{2 - \rho}$$

(a) (3 + 3 points)

Find the form of $n_2^{(g)}$ and $n_3^{(g)}$, the fraction of groups that are of size 2 and size 3.

(b) Using data for James Joyce's Ulysses (see below), first show that Simon's estimate for the innovation rate $\rho_{\text{est}} \simeq 0.115$ is reasonably accurate for the version of the text's word counts given below.

Hint: You should find a slightly higher number than Simon did.

Hint: Do not compute ρ_{est} from an estimate of γ .

- (c) Now compare the theoretical estimates for $n_1^{(g)}$, $n_2^{(g)}$, and $n_3^{(g)}$, with empirical values you obtain for Ulysses.

The data (links are clickable):

- Matlab file (sortedcounts = word frequency f in descending order, sortedwords = ranked words):
<http://www.uvm.edu/pdodds/teaching/courses/2017-08UVM-300/docs/ulysses.mat>
- Colon-separated text file (first column = word, second column = word frequency f):
<http://www.uvm.edu/pdodds/teaching/courses/2017-08UVM-300/docs/ulysses.txt>

Data taken from <http://www.doc.ic.ac.uk/~rac101/concord/texts/ulysses/>. Note that some matching words with differing capitalization are recorded as separate words.
