## Superstars

### Rosen's theory:

- Individual quality  $q$  maps to reward  $R(q)$ .
- $R(q)$  is 'convex' ( $d^2R/dq^2 > 0$ ).
- Two reasons:
  - Imperfect substitution:**  
A very good surgeon is worth many mediocre ones
  - Technology:**  
Media spreads & technology reduces cost of reproduction of books, songs, etc.
- Joint consumption versus public good.
- No social element—success follows 'inherent quality'.

## Outline

Winning: it's not for everyone  
Superstars  
Musiclab

## References

## Where do superstars come from?

"The economics of superstars"  
S. Rosen,  
Am. Econ. Rev., **71**, 845–858, 1981. [5]

### Examples:

- Full-time Comedians ( $\approx 200$ )
- Soloists in Classical Music
- Economic Textbooks (the usual myopic example)

Highly skewed distributions again...

## Superstars

"Stardom and Talent"  
Moshe Adler,  
American Economic Review, **75**, 208–212,  
1985. [1]

- "Consumption capital": "Appreciation [of music] increases with knowledge. But how does one know about music? By listening to it, *and discussing it with other persons who know about it.*"
- Assumes extreme case of equal 'inherent quality'
- Argues desire for coordination in knowledge and culture leads to differential success
- Success can be purely a social construction
- (How can we measure 'inherent quality?')

5 of 26

## Voting

### Evidence from the web suggestions (Huberman et al.)

- Easy decisions (yes/no) lead to bandwagoning  
e.g. jyte.com
  - More costly evaluations lead to oppositional votes  
e.g. amazon.com
- Self-selection:** Costly voting may lower incentives for those who agree with the current assessment and increase incentives for those who disagree.

## Voting

"Aggregating partial, local evaluations to achieve global ranking"  
Laureti, Moret, and Zhang,  
Physica A, **345**, 705–712, 2004. [4]

- Model: participants rank  $n$  objects based on underlying quality  $q$
- Assume evaluation of object  $i$  is a random variable with mean  $q_i$
- Choose objects based on votes:

$$p_i(t) \propto v_i(t)^\alpha \text{ or } p_i(t) \propto q_i v_i(t)^\alpha.$$

- If  $\alpha < 1$ , correct quality ordering is uncovered
- If  $\alpha > 1$ , some objects are never evaluated and mistakes are made...
- Related to Adler's approach

# Music Lab Experiment

## Sensible result:

- Stronger social signal leads to **greater following** and **greater inequality**.

## Peculiar result:

- Stronger social signal leads to greater **unpredictability**.

## Very peculiar observation:

- The most unequal distributions would suggest the greatest variation in underlying 'quality.'
- But success may be due to social construction through **following**. (so let's tell a story... [8, 9])

# Music Lab Experiment—Sneakiness [7]
