Red Hat Enterprise Linux 6
Deployment Guide

Deployment, Configuration and Administration of Red Hat Enterprise Linux 6

Douglas Silas
Martin Prpič
Florian Nadge
Jaromír Hradílek
John Ha
David O'Brien
Michael Hideo
Don Domingo
The Deployment Guide documents relevant information regarding the deployment, configuration and administration of Red Hat Enterprise Linux 6.
# Preface

# Introduction

I. Package Management

1. Yum
   1.1. Checking For and Updating Packages ............................................................................. 3
       1.1.1. Checking For Updates ............................................................................................ 3
       1.1.2. Updating Packages ............................................................................................... 4
       1.1.3. Updating Security-Related Packages ........................................................................ 5
       1.1.4. Preserving Configuration File Changes .................................................................. 5
   1.2. Packages and Package Groups ....................................................................................... 6
       1.2.1. Searching, Listing and Displaying Package Information ........................................ 6
       1.2.2. Installing .............................................................................................................. 9
       1.2.3. Removing ........................................................................................................... 11
   1.3. Configuring Yum and Yum Repositories ......................................................................... 11
       1.3.1. Setting [main] Options ......................................................................................... 12
       1.3.2. Setting [repository] Options ................................................................................. 15
       1.3.3. Using Yum Variables ............................................................................................ 16
       1.3.4. Creating a Yum Repository .................................................................................. 16
   1.4. Yum Plugins .................................................................................................................... 17
       1.4.1. Enabling, Configuring and Disabling Yum Plugins ............................................... 17
       1.4.2. Installing More Yum Plugins ................................................................................. 18
       1.4.3. Plugin Descriptions ............................................................................................. 19
   1.5. Additional Resources ..................................................................................................... 20

2. PackageKit
   2.1. Updating Packages with Software Update ...................................................................... 21
   2.2. Using Add/Remove Software .......................................................................................... 23
       2.2.1. Refreshing Software Sources (Yum Repositories) ............................................... 24
       2.2.2. Finding Packages with Filters ............................................................................... 25
       2.2.3. Installing and Removing Packages (and Dependencies) ....................................... 27
       2.2.4. Installing and Removing Package Groups .............................................................. 29
       2.2.5. Viewing the Transaction Log .................................................................................. 29
   2.3. PackageKit Architecture ................................................................................................. 30
   2.4. Additional Resources ..................................................................................................... 31

3. RPM
   3.1. RPM Design Goals .......................................................................................................... 34
   3.2. Using RPM ...................................................................................................................... 34
       3.2.1. Finding RPM Packages ......................................................................................... 35
       3.2.2. Installing and Upgrading ...................................................................................... 35
       3.2.3. Configuration File Changes ................................................................................... 38
       3.2.4. Uninstalling ............................................................................................................ 38
       3.2.5. Freshening ............................................................................................................. 39
       3.2.6. Querying ................................................................................................................. 40
       3.2.7. Verifying ............................................................................................................... 41
# 8. Authentication Configuration

8.1. The Authentication Configuration Tool ......................................................... 87
   8.1.1. Identity & Authentication ........................................................................ 87
   8.1.2. Advanced Options ............................................................................... 90
   8.1.3. Command Line Version ...................................................................... 92

8.2. The System Security Services Daemon (SSSD) .............................................. 95
   8.2.1. What is SSSD? ................................................................................... 96
   8.2.2. SSSD Features ................................................................................. 96
   8.2.3. Setting Up SSSD ............................................................................. 98
   8.2.4. Configuring Services ....................................................................... 105
   8.2.5. Configuring Domains ...................................................................... 106
   8.2.6. Setting Up Kerberos Authentication ............................................... 114
   8.2.7. Troubleshooting ............................................................................. 115
   8.2.8. SSSD Configuration File Format ....................................................... 119

# 9. OpenSSH

9.1. The SSH Protocol .................................................................................... 121
   9.1.1. Why Use SSH? ............................................................................... 121
   9.1.2. Main Features ................................................................................. 121
   9.1.3. Protocol Versions ........................................................................... 122
   9.1.4. Event Sequence of an SSH Connection ........................................... 122

9.2. An OpenSSH Configuration ...................................................................... 124
   9.2.1. Configuration Files ......................................................................... 124
   9.2.2. Starting an OpenSSH Server ............................................................ 126
   9.2.3. Requiring SSH for Remote Connections ......................................... 126
   9.2.4. Using a Key-Based Authentication .................................................. 127

9.3. OpenSSH Clients .................................................................................... 132
   9.3.1. Using the ssh Utility ........................................................................ 132
   9.3.2. Using the scp Utility ....................................................................... 133
   9.3.3. Using the sftp Utility ....................................................................... 134

9.4. More Than a Secure Shell ......................................................................... 134
   9.4.1. X11 Forwarding .............................................................................. 135
   9.4.2. Port Forwarding ............................................................................... 135

9.5. Additional Resources ............................................................................... 136
   9.5.1. Installed Documentation .................................................................. 136
   9.5.2. Useful Websites .............................................................................. 137

# 10. The BIND DNS Server

10.1. Introduction to DNS ............................................................................. 139
   10.1.1. Nameserver Zones ....................................................................... 139
   10.1.2. Nameserver Types ....................................................................... 139
   10.1.3. BIND as a Nameserver ................................................................. 140

10.2. Configuring the named Service ............................................................... 140
   10.2.1. Common Statement Types .............................................................. 141
   10.2.2. Other Statement Types .................................................................. 146
   10.2.3. Comment Tags .............................................................................. 147

10.3. Editing Zone Files .................................................................................. 148
   10.3.1. Common Directives ...................................................................... 148

A. Revision History .................................................................................................. 407

Index ......................................................................................................................... 409
Preface

1. Document Conventions

This manual uses several conventions to highlight certain words and phrases and draw attention to specific pieces of information.

In PDF and paper editions, this manual uses typefaces drawn from the Liberation Fonts\(^1\) set. The Liberation Fonts set is also used in HTML editions if the set is installed on your system. If not, alternative but equivalent typefaces are displayed. Note: Red Hat Enterprise Linux 5 and later includes the Liberation Fonts set by default.

1.1. Typographic Conventions

Four typographic conventions are used to call attention to specific words and phrases. These conventions, and the circumstances they apply to, are as follows.

**Mono-spaced Bold**

Used to highlight system input, including shell commands, file names and paths. Also used to highlight keycaps and key combinations. For example:

To see the contents of the file *my_next_bestselling_novel* in your current working directory, enter the `cat my_next_bestselling_novel` command at the shell prompt and press `Enter` to execute the command.

The above includes a file name, a shell command and a keycap, all presented in mono-spaced bold and all distinguishable thanks to context.

Key combinations can be distinguished from keycaps by the hyphen connecting each part of a key combination. For example:

Press `Enter` to execute the command.

Press `Ctrl+Alt+F2` to switch to the first virtual terminal. Press `Ctrl+Alt+F1` to return to your X-Windows session.

The first paragraph highlights the particular keycap to press. The second highlights two key combinations (each a set of three keycaps with each set pressed simultaneously).

If source code is discussed, class names, methods, functions, variable names and returned values mentioned within a paragraph will be presented as above, in *mono-spaced bold*. For example:

File-related classes include *filesystem* for file systems, *file* for files, and *dir* for directories. Each class has its own associated set of permissions.

**Proportional Bold**

This denotes words or phrases encountered on a system, including application names; dialog box text; labeled buttons; check-box and radio button labels; menu titles and sub-menu titles. For example:

Choose **System → Preferences → Mouse** from the main menu bar to launch **Mouse Preferences**. In the **Buttons** tab, click the **Left-handed mouse** check box and click

---

\(^1\) https://fedorahosted.org/liberation-fonts/
Close to switch the primary mouse button from the left to the right (making the mouse suitable for use in the left hand).

To insert a special character into a gedit file, choose Applications \rightarrow Accessories \rightarrow Character Map from the main menu bar. Next, choose Search \rightarrow Find… from the Character Map menu bar, type the name of the character in the Search field and click Next. The character you sought will be highlighted in the Character Table. Double-click this highlighted character to place it in the Text to copy field and then click the Copy button. Now switch back to your document and choose Edit \rightarrow Paste from the gedit menu bar.

The above text includes application names; system-wide menu names and items; application-specific menu names; and buttons and text found within a GUI interface, all presented in proportional bold and all distinguishable by context.

Mono-spaced Bold Italic or Proportional Bold Italic

Whether mono-spaced bold or proportional bold, the addition of italics indicates replaceable or variable text. Italics denotes text you do not input literally or displayed text that changes depending on circumstance. For example:

To connect to a remote machine using ssh, type ssh \texttt{username@domain.name} at a shell prompt. If the remote machine is example.com and your username on that machine is john, type ssh \texttt{john@example.com}.

The \texttt{mount -o remount file-system} command remounts the named file system. For example, to remount the \texttt{/home} file system, the command is \texttt{mount -o remount /home}.

To see the version of a currently installed package, use the \texttt{rpm -q \textit{package}} command. It will return a result as follows: \texttt{package-version-release}.

Note the words in bold italics above — username, domain.name, file-system, package, version and release. Each word is a placeholder, either for text you enter when issuing a command or for text displayed by the system.

Aside from standard usage for presenting the title of a work, italics denotes the first use of a new and important term. For example:

Publican is a \textit{DocBook} publishing system.

1.2. Pull-quote Conventions

Terminal output and source code listings are set off visually from the surrounding text.

Output sent to a terminal is set in mono-spaced roman and presented thus:

\begin{verbatim}
books        Desktop   documentation  drafts  mss    photos   stuff  svn
books_tests  Desktop1  downloads      images  notes  scripts  svgs
\end{verbatim}

Source-code listings are also set in mono-spaced roman but add syntax highlighting as follows:

\begin{verbatim}
package org.jboss.book.jca.ex1;
import javax.naming.InitialContext;
\end{verbatim}
public class ExClient
{
    public static void main(String args[])
    throws Exception
    {
        InitialContext iniCtx = new InitialContext();
        Object ref = iniCtx.lookup("EchoBean");
        EchoHome home = (EchoHome) ref;
        Echo echo = home.create();

        System.out.println("Created Echo");

        System.out.println("Echo.echo('Hello') = " + echo.echo("Hello"));
    }
}

1.3. Notes and Warnings
Finally, we use three visual styles to draw attention to information that might otherwise be overlooked.

Note
Notes are tips, shortcuts or alternative approaches to the task at hand. Ignoring a note should have no negative consequences, but you might miss out on a trick that makes your life easier.

Important
Important boxes detail things that are easily missed: configuration changes that only apply to the current session, or services that need restarting before an update will apply. Ignoring a box labeled 'Important' will not cause data loss but may cause irritation and frustration.

Warning
Warnings should not be ignored. Ignoring warnings will most likely cause data loss.

2. We Need Feedback!
If you find a typographical error in this manual, or if you have thought of a way to make this manual better, we would love to hear from you! Please submit a report in Bugzilla: http://bugzilla.redhat.com/ against the product Red Hat Enterprise Linux 6.

If you have a suggestion for improving the documentation, try to be as specific as possible when describing it. If you have found an error, please include the section number and some of the surrounding text so we can find it easily.

2.1. Technical Review Requests
All review requests are classified into one of the following five categories:
New Content
content documented for the first time — an entirely new feature, procedure, or concept. For example: "Section now describes the new procedure for creating bootable USB devices."

Correction
a factual error previously present in the text has been corrected. For example: "Section previously stated (incorrectly) that IPv4 and IPv6 were both supported; section now states that IPv6 has never been supported."

Clarification
material that was already factually correct but is now better explained. Clarifications are usually in response to reader feedback that the previous content was confusing or misleading in some way. For example: "Paths described in Example 1.2.3 now better reflect the directory structure of an actual installed system."

Obsoletion
a description of a feature or a procedure has been dropped. Material might be obsolete because of a feature that is no longer supported, a known issue that has been corrected, or hardware that is now obsolete. For example, "Section no longer describes how to update kernel modules using a floppy disk."

Verification
a request to check a fact, procedure, or whether material should be obsoleted. For example, "Section describes how to connect to a generic iSCSI storage device. Please verify this on your hardware" or "Section still describes how to update kernel modules using a LS-120 SuperDisk; please verify that we still need to tell readers about this obsolete hardware."

3. Acknowledgements

The authors of this book would like to thank the following people for their valuable contributions: Adam Tkáč, Andrew Fitzsimon, Andrius Benokraitis, Brian Cleary Edward Bailey, Garrett LeSage, Jeffrey Fearn, Joe Orton, Joshua Wulf, KarstenWade, Lucy Ringland, Marcela Mašláňová, Mark Johnson, Michael Behm, Michael Behm, Miroslav Lichvár, Radek Vokál, Rahul Kavalapara, Rahul Sundaram, Sandra Moore, and Zbyšek Mráz, among many others.
Introduction

Welcome to the Red Hat Enterprise Linux 6 Deployment Guide.

The Deployment Guide contains information on how to customize your Red Hat Enterprise Linux 6 system to fit your needs. If you are looking for a comprehensive, task-oriented guide for configuring and customizing your system, this is the manual for you.

This manual discusses many intermediate topics such as the following:

• Installing and managing packages using the graphical PackageKit and command line Yum package managers

• Setting up a network—from establishing an Ethernet connection using NetworkManager to configuring channel bonding interfaces to increase server bandwidth

• Configuring DHCP, BIND, Apache, Postfix, Sendmail and other enterprise-class servers and software

• Gathering information about your system, including obtaining user-space crash data with the Automatic Bug Reporting Tool, and kernel-space crash data with kdump

• Easily working with kernel modules and upgrading the kernel

This manual is divided into the following main categories:

• Part I, “Package Management”

• Part II, “Network-Related Configuration”

• Part III, “System Configuration”

• Part IV, “System Monitoring”

• Part V, “Kernel, Module and Driver Configuration”

This guide assumes you have a basic understanding of your Red Hat Enterprise Linux system. If you need help installing Red Hat Enterprise Linux, refer to the Red Hat Enterprise Linux 6 Installation Guide.
Part I. Package Management

All software on a Red Hat Enterprise Linux system is divided into RPM packages, which can be installed, upgraded, or removed. This part describes how to manage packages on Red Hat Enterprise Linux using the Yum and RPM package managers and the PackageKit suite of graphical package management tools.
Yum

Yum is the Red Hat package manager that is able to query for information about packages, fetch packages from repositories, install and uninstall packages using automatic dependency resolution, and update an entire system to the latest available packages. Yum performs automatic dependency resolution on packages you are updating, installing or removing, and thus is able to automatically determine, fetch and install all available dependent packages. Yum can be configured with new, additional repositories, or package sources, and also provides many plugins which enhance and extend its capabilities. Yum is able to perform many of the same tasks that RPM can; additionally, many of the command line options are similar. Yum enables easy and simple package management on a single machine or on groups of them.

Secure Package Management with GPG-Signed Packages

Yum provides secure package management by enabling GPG (Gnu Privacy Guard; also known as GnuPG) signature verification on GPG-signed packages to be turned on for all package repositories (i.e. package sources), or for individual repositories. When signature verification is enabled, Yum will refuse to install any packages not GPG-signed with the correct key for that repository. This means that you can trust that the RPM packages you download and install on your system are from a trusted source, such as Red Hat, and were not modified during transfer. Refer to Section 1.3, “Configuring Yum and Yum Repositories” for details on enabling signature-checking with Yum, or Section 3.3, “Checking a Package’s Signature” for information on working with and verifying GPG-signed RPM packages in general.

Yum also enables you to easily set up your own repositories of RPM packages for download and installation on other machines.

Learning Yum is a worthwhile investment because it is often the fastest way to perform system administration tasks, and it provides capabilities beyond those provided by the PackageKit graphical package management tools. Refer to Chapter 2, PackageKit for details on using PackageKit.

1.1. Checking For and Updating Packages

1.1.1. Checking For Updates

You can use the yum check-update command to see which installed packages on your system have updates available.

Note: Yum and Superuser Privileges

You must have superuser privileges in order to use yum to install, update or remove packages on your system. All examples in this chapter assume that you have already obtained superuser privileges by using either the su or sudo command.

```bash
$ yum check-update
Loaded plugins: presto, refresh-packagekit, security
PackageKit.x86_64             0.5.8-2.el6              rhel
PackageKit-glib.x86_64        0.5.8-2.el6              rhel
```
These packages are listed as having updates available. The first package in the list is `PackageKit`, the graphical package manager. The first line of the above output tells us:

- **PackageKit** — the name of the package
- **x86_64** — the CPU architecture the package was built for
- **0.5.8** — the version of the updated package to be installed
- **rhel** — the repository in which the updated package is located

The output also shows us that we can update the kernel (the kernel package), **Yum** and **RPM** themselves (the `yum` and `rpm` packages), as well as their dependencies (such as the `kernel-firmware`, `rpm-libs` and `rpm-python` packages), all using **yum**.

### 1.1.2. Updating Packages

You can choose to update a single package, multiple packages, or all packages at once. If any dependencies of the package (or packages) you update have updates available themselves, then they are updated too. To update a single package, enter `yum update <package_name>`:

```
~]$ yum update udev
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
Setting up Update Process
Resolving Dependencies
---> Running transaction check
---> Package udev.x86_64 0:147-2.15.el6 set to be updated
---> Finished Dependency Resolution
Dependencies Resolved
===========================================================================
Package       Arch            Version                 Repository     Size
===========================================================================
Updating:
udev          x86_64          147-2.15.el6            rhel          337 k
Transaction Summary
===========================================================================
Install       0 Package(s)
Upgrade       1 Package(s)
Total download size: 337 k
Is this ok [y/N]:
```

This output contains several items of interest:

1. **Loaded plugins: presto, refresh-packagekit, security** — **yum** always informs you which **Yum** plugins are installed and enabled. Here, **yum** is using the `presto`, `refresh-packagekit` and `security` plugins. Refer to **Section 1.4, “Yum Plugins”** for general information on **Yum** plugins, or to **Section 1.4.3, “Plugin Descriptions”** for descriptions of specific plugins.
2. **kernel.x86_64** — you can download and install new kernels safely with **yum**.

### Important: Updating and Installing Kernels with Yum

**yum** always installs a new kernel in the same sense that **RPM** installs a new kernel when you use the command **rpm -i kernel**. Therefore, you do not need to worry about the distinction between installing and upgrading a kernel package when you use **yum**: it will do the right thing, regardless of whether you are using the **yum update** or **yum install** command.

When using **RPM**, on the other hand, it is important to use the **rpm -i kernel** command (which installs a new kernel) instead of **rpm -u kernel** (which replaces the current kernel). Refer to Section 3.2.2, "Installing and Upgrading" for more information on installing/updating kernels with **RPM**.

3. **yum** presents the update information and then prompts you as to whether you want it to perform the update; **yum** runs interactively by default. If you already know which transactions **yum** plans to perform, you can use the `-y` option to automatically answer **yes** to any questions **yum** may ask (in which case it runs non-interactively). However, you should always examine which changes **yum** plans to make to the system so that you can easily troubleshoot any problems that might arise.

If a transaction does go awry, you can view **Yum**'s log of transactions by entering `cat /var/log/yum.log` at the shell prompt. The most recent transactions are listed at the end of the log file.

### Updating All Packages and Their Dependencies

To update all packages and their dependencies, simply enter **yum update** (without any arguments):

**Example 1.1. Updating all packages at once**

```
~]$ yum update
```

#### 1.1.3. Updating Security-Related Packages

Discovering which packages have security updates available and then updating those packages quickly and easily is important. **Yum** provides the plugin for this purpose. The **security** plugin extends the **yum** command with a set of highly-useful security-centric commands, subcommands and options. Refer to Section 1.4.3, "security (yum-plugin-security)" for specific information.

#### 1.1.4. Preserving Configuration File Changes

You will inevitably make changes to the configuration files installed by packages as you use your Red Hat Enterprise Linux system. **RPM**, which **Yum** uses to perform changes to the system, provides a mechanism for ensuring their integrity. Refer to Section 3.2.2, "Installing and Upgrading" for details on how to manage changes to configuration files across package upgrades.
Chapter 1. Yum

1.2. Packages and Package Groups

1.2.1. Searching, Listing and Displaying Package Information

You can search all RPM package names, descriptions and summaries by using the `yum search <term> [more_terms]` command. `yum` displays the list of matches for each term:

```bash
~]# yum search meld kompare
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
============================ Matched: kompare =============================
kdesdk.x86_64 : The KDE Software Development Kit (SDK)
Warning: No matches found for: meld
```

`yum search` is useful for searching for packages you do not know the name of, but for which you know a related term.

Listing Packages

`yum list` and related commands provide information about packages, package groups, and repositories.
Tip: Filtering Results with Glob Expressions

All of Yum’s various list commands allow you to filter the results by appending one or more glob expressions as arguments. Glob expressions are normal strings of characters which contain one or more of the wildcard characters * (which expands to match any character multiple times) and ? (which expands to match any one character). Be careful to escape both of these glob characters when passing them as arguments to a yum command. If you do not, the bash shell will interpret the glob expressions as pathname expansions, and potentially pass all files in the current directory that match the globs to yum, which is not what you want. Instead, you want to pass the glob expressions themselves to yum, which you can do by either:

• escaping the wildcard characters

• double-quoting or single-quoting the entire glob expression.

The following examples show both methods:

Example 1.2. Filtering results using a single glob expression with two escaped wildcard characters

```bash
~]# yum list available gstreamer\'*\plugin\'*
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
Available Packages
  gstreamer-plugins-bad-free.i686 0.10.17-4.el6  rhel
  gstreamer-plugins-base.i686    0.10.26-1.el6  rhel
  gstreamer-plugins-base-devel.i686 0.10.26-1.el6 rhel
  gstreamer-plugins-base-devel.x86_64 0.10.26-1.el6 rhel
  gstreamer-plugins-good.i686    0.10.18-1.el6  rhel
```

Example 1.3. Filtering results using a double-quoted glob expression

```bash
~]# yum list installed "krb?-*"
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
Installed Packages
  krb5-libs.x86_64                         1.8.1-3.el6          @rhel
  krb5-workstation.x86_64                  1.8.1-3.el6          @rhel
```

• yum list <glob_expr> [more_glob_exprs] — List information on installed and available packages matching all glob expressions.

Example 1.4. Listing all ABRT addons and plugins using glob expressions

```bash
~]# yum list abrt-addon\'*\ abrt-plugin\'*
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
Installed Packages
  abrt-addon-ccpp.x86_64                    1.0.7-5.el6         @rhel
  abrt-addon-kerneloops.x86_64             1.0.7-5.el6         @rhel
  abrt-addon-python.x86_64                 1.0.7-5.el6         @rhel
  abrt-plugin-bugzilla.x86_64              1.0.7-5.el6         @rhel
  abrt-plugin-logger.x86_64                1.0.7-5.el6         @rhel
  abrt-plugin-sosreport.x86_64             1.0.7-5.el6         @rhel
  abrt-plugin-ticketuploader.x86_64        1.0.7-5.el6         @rhel
```
Chapter 1. Yum

- **yum list all** — List all installed and available packages.

- **yum list installed** — List all packages installed on your system. The rightmost column in the output lists the repository from which the package was retrieved.

- **yum list available** — List all available packages in all enabled repositories.

- **yum grouplist** — List all package groups.

- **yum repolist** — List the repository ID, name, and number of packages it provides for each enabled repository.

### Displaying Package Info

**yum info <package_name> [more_names]** displays information about one or more packages (glob expressions are valid here as well):

```bash
-# yum info abrt
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
Installed Packages
Name : abrt
Arch : x86_64
Version : 1.0.7
Release : 5.el6
Size : 578 k
Repo : installed
From repo : rhel
Summary : Automatic bug detection and reporting tool
URL : https://fedorahosted.org/abrt/
License : GPLv2+
Description: abrt is a tool to help users to detect defects in applications
and to create a bug report with all informations needed by
maintainer to fix it. It uses plugin system to extend its
functionality.
```

**yum info <package_name>** is similar to the **rpm -q --info <package_name>** command, but provides as additional information the ID of the Yum repository the RPM package is found in (look for the From repo: line in the output).

**yumdb info <package_name> [more_names]** can be used to query the Yum database for alternative and useful information about a package, including the checksum of the package (and algorithm used to produce it, such as SHA-256), the command given on the command line that was invoked to install the package (if any), and the reason that the package is installed on the system (where **user** indicates it was installed by the user, and **dep** means it was brought in as a dependency):

```bash
-# yumdb info yum
yum-3.2.27-4.el6.noarch
checksum_data = 15c8eaf583fabad6974a35b9f6c6527e49362fe4e23baec1682ef51a598e4abb
checksum_type = sha256
command_line = update
from_repo = rhel
from_repo_revision = 1271991599
from_repo_timestamp = 1271991721
reason = user
```
See `man yumdb` for more information on the `yumdb` command.

Finally, the `yum history` command, which is new in Red Hat Enterprise Linux 6, can be used to show a timeline of Yum transactions, the dates and times on when they occurred, the number of packages affected, whether transactions succeeded or were aborted, and if the RPM database was changed between transactions. Refer to the `history` section of `man yum` for details.

### 1.2.2. Installing

You can install a package and all of its non-installed dependencies by entering:

```bash
~]# yum install <package_name>
```

You can install multiple packages simultaneously by appending their names as arguments: `yum install <package_name> [more_names]`.

If you are installing packages on a multilib system, such as an AMD64 or Intel64 machine, you can specify the architecture of the package (as long as it's available in an enabled repository) by appending `.arch` to the package name:

```bash
~]# yum install sqlite2.i586
```

You can use glob expressions to quickly install multiple similarly-named packages:

```bash
~]# yum install audacious-plugins-\*
```

In addition to package names and glob expressions, you can also provide file names to `yum install`. If you know the name of the binary you want to install, but not its package name, you can give `yum install` the path name:

```bash
~]# yum install /usr/sbin/named
```

`yum` then searches through its package lists, finds the package which provides `/usr/sbin/named`, if any, and prompts you as to whether you want to install it.

What if you know you want to install the package that contains the `named` binary, but don't know in which bin or sbin directory that file lives? In that situation, you can give `yum provides` a glob expression:

#### Example 1.5. Finding which package owns a file and installing it

```bash
~]# yum provides "*bin/named"
Loaded plugins: presto, refresh-packagekit, rhnplugin, security
32:bind-9.7.0-4.P1.el6.x86_64 : The Berkeley Internet Name Domain (BIND) : DNS (Domain Name System) server
Repo        : rhel
Matched from:
Filename    : /usr/sbin/named
~]# yum install bind
```
**Note**

*Note* that obtaining and installing software packages from unverified or untrusted software sources other than Red Hat Network constitutes a potential security risk, and could lead to security, stability, compatibility maintainability issues.

**Tip: yum provides/whatprovides and Glob Expressions**

*Note that* *yum provides* "*/<file_name>" *is a common and useful trick to quickly find the package(s) that contain <file_name>.

---

**Installing a Package Group**

A package group is similar to a package: it is not useful by itself, but installing one pulls a group of dependent packages that serve a common purpose. A package group has a name and a groupid. The *yum grouplist* -v command lists the names of all package groups, and, next to each of them, their *groupid* in parentheses. The groupid is always the term in the last pair of parentheses, such as *kde-desktop* and *kde-software-development* in this example:

Not all packages used in examples may be available on RHN

Some of the software packages—or package groups—queried for and installed with *Yum* in this chapter may not be available from Red Hat Network. Their use in examples is purely to demonstrate *Yum’s* command usage.

You can install a package group by passing its full group name (without the groupid part) to *groupinstall*:

```
~# yum -v grouplist kde*
KDE (K Desktop Environment) (kde-desktop)
KDE Software Development (kde-software-development)
```

You can also install by groupid:

```
~# yum groupinstall kde-desktop
```

You can even pass the groupid (or quoted name) to the *install* command if you prepend it with an @-symbol (which tells *yum* that you want to perform a *groupinstall*):

```
~# yum install @kde-desktop
```
1.2.3. Removing

**yum remove** `<package_name>`
uninstalls (removes in **RPM** and **Yum** terminology) the package, as well as any packages that depend on it. As when you install multiple packages, you can remove several at once by adding more package names to the command:

```bash
yum remove foo bar baz
```

Similar to **install**, **remove** can take these arguments:
- package names
- glob expressions
- file lists
- package provides

---

**Warning: Removing a Package when Other Packages Depend On It**

**Yum** is not able to remove a package without also removing packages which depend on it. This type of operation can only be performed by **RPM**, is not advised, and can potentially leave your system in a non-functioning state or cause applications to misbehave and/or crash. For further information, refer to **Section 3.2.4, “Uninstalling”** in the **RPM** chapter.

---

### Removing a Package Group

You can remove a package group using syntax congruent with the **install** syntax.

**Example 1.6. Alternative but equivalent ways of removing a package group**

```bash
~# yum groupremove "KDE (K Desktop Environment)"
~# yum groupremove kde-desktop
~# yum remove @kde-desktop
```

---

**Smart package group removal**

When you tell **yum** to remove a package group, it will remove every package in that group, even if those packages are members of other package groups or dependencies of other installed packages. However, you can instruct **yum** to remove only those packages which are not required by any other packages or groups by adding the `groupremove_leaf_only=1` directive to the `[main]` section of the `/etc/yum.conf` configuration file. For more information on this directive, refer to **Section 1.3.1, “Setting [main] Options”**.

---

1.3. Configuring Yum and Yum Repositories

This section shows you how to:

- set global **Yum** options by editing the `[main]` section of the `/etc/yum.conf` configuration file;
Chapter 1. Yum

- set options for individual repositories by editing the [repository] sections in /etc/yum.conf and .repo files in the /etc/yum.repos.d/ directory;
- use Yum variables in /etc/yum.conf and files in /etc/yum.repos.d/so that dynamic version and architecture values are handled correctly; and,
- set up your own custom Yum repository.

The /etc/yum.conf configuration file contains one mandatory [main] section under which you can set Yum options. The values that you define in the [main] section of yum.conf have global effect, and may override values set any individual [repository] sections. You can also add [repository] sections to /etc/yum.conf; however, best practice is to define individual repositories in new or existing .repo files in the /etc/yum.repos.d/directory. Refer to Section 1.3.2, “Setting [repository] Options” if you need to add or edit repository-specific information.

1.3.1. Setting [main] Options

The /etc/yum.conf configuration file contains exactly one [main] section. You can add many additional options under the [main] section heading in /etc/yum.conf. Some of the key-value pairs in the [main] section affect how yum operates; others affect how Yum treats repositories. The best source of information for all Yum options is in the [main] OPTIONS and [repository] OPTIONS sections of man yum.conf.

Here is a sample /etc/yum.conf configuration file:

```conf
[main]
cachedir=/var/cache/yum/$basearch/$releasever
keepcache=0
debuflevel=2
logfile=/var/log/yum.log
exactarch=1
obsoletes=1
gpgcheck=1
plugins=1
installonly_limit=3
[comments abridged]
# PUT YOUR REPOS HERE OR IN separate files named file.repo
# in /etc/yum.repos.d
```

Here is a list of the most commonly-used options in the [main] section, and descriptions for each:

assumeyes=<value>

...where <value> is one of:

0 — yum should prompt for confirmation of critical actions it performs. This is the default.

1 — Do not prompt for confirmation of critical yum actions. If assumeyes=1 is set, yum behaves in the same way that the command line option -y does.

cachedir=/var/cache/yum/$basearch/$releasever

This option specifies the directory where Yum should store its cache and database files. By default, Yum’s cache directory is /var/cache/yum/$basearch/$releasever. See Section 1.3.3, “Using Yum Variables” for descriptions of the $basearch and $releasever Yum variables.
Setting [main] Options

debuglevel=value
...where <value> is an integer between 1 and 10. Setting a higher debuglevel value causes yum to display more detailed debugging output. debuglevel=0 disables debugging output, while debuglevel=2 is the default.

exactarch=<value>
...where <value> is one of:

0 — Do not take into account the exact architecture when updating packages.

1 — Consider the exact architecture when updating packages. With this setting, yum will not install an i686 package to update an i386 package already installed on the system. This is the default.

exclude=<package_name> [more_package_names]
This option allows you to exclude packages by keyword during installation/updates. Listing multiple packages for exclusion can be accomplished by quoting a space-delimited list of packages. Shell globs using wildcards (for example, * and ?) are allowed.

gpgcheck=<value>
...where <value> is one of:

0 — Disable GPG signature-checking on packages in all repositories, including local package installation.

1 — Enable GPG signature-checking on all packages in all repositories, including local package installation. gpgcheck=1 is the default, and thus all packages' signatures are checked.

If this option is set in the [main] section of the /etc/yum.conf file, it sets the GPG-checking rule for all repositories. However, you can also set gpgcheck= <value> for individual repositories instead; i.e., you can enable GPG-checking on one repository while disabling it on another. Setting gpgcheck=<value> for an individual repository in its corresponding .repo file overrides the default if it is present in /etc/yum.conf. Refer to Section 3.3, “Checking a Package's Signature” for further information on GPG signature-checking.

grouprecmove_leaf_only=<value>
...where <value> is one of:

0 — yum should not check the dependencies of each package when removing a package group. With this setting, yum removes all packages in a package group, regardless of whether those packages are required by other packages or groups. groupremove_leaf_only=0 is the default.

1 — yum should check the dependencies of each package when removing a package group, and remove only those packages which are not not required by any other package or group.

For more information on removing packages, refer to Smart package group removal.

installonlypkgs=<space> <separated> <list> <of> <packages>
Here you can provide a space-separated list of packages which yum can install, but will never update. Refer to man yum.conf for the list of packages which are install-only by default. If you add the installonlypkgs directive to /etc/yum.conf, you should ensure that you list all of the packages that should be install-only, including any of those listed under the installonlypkgs section of man yum.conf. In particular, kernel packages should always be listed in installonlypkgs (as they are by default), and installonly_limit should always be set to a value greater than 2 so that a backup kernel is always available in case the default one fails to boot. Refer to installonly_limit=??? for details on the installonly_limit directive.
installonly_limit=<value>

...where <value> is an integer representing the maximum number of versions that can be installed simultaneously for any single package listed in the installonlypkgs directive. The defaults for the installonlypkgs directive include several different kernel packages, so be aware that changing the value of installonly_limit will also affect the maximum number of installed versions of any single kernel package. The default value listed in /etc/yum.conf is installonly_limit=3, and it is not recommended to decrease this value, particularly below 2.

keepcache=<value>

...where value is one of:

0 — Do not retain the cache of headers and packages after a successful installation. This is the default.

1 — Retain the cache after a successful installation.

logfile=/var/log/yum.log

This option specifies where yum should send its logging output. By default, yum logs to /var/log/yum.log.

multilib_policy=<value>

...where <value> is one of:

best — install the best-choice architecture for this system. For example, setting multilib_policy=best on an AMD64 system causes yum to install 64-bit versions of all packages.

all — always install every possible architecture for every package. For example, with multilib_policy set to all on an AMD64 system, yum would install both the i586 and AMD64 versions of a package, if both were available.

obsoletes=<value>

...where <value> is one of:

0 — Disable yum's obsoletes processing logic when performing updates.

1 — Enable yum's obsoletes processing logic when performing updates. When one package declares in its spec file that it obsoletes another package, the latter package will be replaced by the former package when the former package is installed. Obsoletes are declared, for example, when a package is renamed. obsoletes=1 the default.

plugins=<value>

...where <value> is one of:

0 — Disable all Yum plugins globally.

Disabling plugins is not advised

Disabling all plugins is not advised because certain plugins provide important Yum services. In particular, rhnplugin enables connecting to Red Hat Network, and the security plugin allows system administrators to easily update the system with (sometimes critical) security updates. Disabling plugins globally is provided as a convenience option, and is generally only recommended when diagnosing a potential problem with Yum.
1 — Enable all Yum plugins globally. With `plugins=1`, you can still disable a specific Yum plugin by setting `enabled=0` in that plugin’s configuration file. Refer to Section 1.4, “Yum Plugins” for more information about various Yum plugins, or to Section 1.4.1, “Enabling, Configuring and Disabling Yum Plugins” for further information on controlling plugins.

`reposdir=<absolute/path/to/directory/containing/repo/files>`

This option allows you to specify a directory where .repo files are located. All .repo files contain repository information (similar to the [repository] section(s) of /etc/yum.conf). yum collects all repository information from .repo files and the [repository] section of the /etc/yum.conf file to create a master list of repositories to use for transactions. Refer to Section 1.3.2, “Setting [repository] Options” for more information about options you can use for both the [repository] section and .repo files. If `reposdir` is not set, yum uses the default directory /etc/yum.repos.d/.

`retries=<value>`

...where `<value>` is an integer 0 or greater. This value sets the number of times yum should attempt to retrieve a file before returning an error. Setting this to 0 makes yum retry forever. The default value is 10.

### 1.3.2. Setting [repository] Options

You can define individual Yum repositories by adding [repository] sections (where repository is a unique repository ID, such as [my_personal_repo]) to /etc/yum.conf or to .repo files in the /etc/yum.repos.d/ directory. All .repo files in /etc/yum.repos.d/ are read by yum; best practice is to define your repositories here instead of in /etc/yum.conf. You can create new, custom .repo files in this directory, add [repository] sections to those files, and the next time you run a yum command, it will take all newly-added repositories into account.

Here is a (bare-minimum) example of the form a .repo file should take:

```
[repository_ID]
name=A Repository Name
baseurl=http://path/to/repo or ftp://path/to/repo or file://path/to/local/repo
```

Every [repository] section must contain the following minimum parts:

**[repository_ID]**

The repository ID is a unique, one-word (no spaces; underscores are allowed) string of characters (enclosed by brackets) that serves as a repository identifier.

**name=**<My Repository Name>

This is a human-readable string describing the repository.

**baseurl=**http://path/to/repo, ftp://path/to/repo, file://path/to/local/repo

This is a URL to the directory where the repodata directory of a repository is located. Usually this URL is an HTTP link, such as:

```
baseurl=http://path/to/repo/releases/$releasever/server/$basearch/os/
```

Yum always expands the $releasever, $arch and $basearch variables in URLs. See the following section for explanations of all Yum variables: Section 1.3.3, “Using Yum Variables”.

- If the repository is available over FTP, use: ftp://path/to/repo
- If the repository is local to the machine, use file://path/to/local/repo
Chapter 1. Yum

- If a specific online repository requires basic HTTP authentication, you can specify your username and password in the `http://path/to/repo` by prepending it as `username:password@link`. For example, if a repository on `http://www.example.com/repo/` requires a username of “user” and a password of “password”, then the `baseurl` link could be specified as:

```
baseurl=http://user:password@www.example.com/repo/
```

The following is another useful `[repository]` directive:

```
enabled=<value>
...where <value> is one of:

0 — do not include this repository as a package source when performing updates and installs. This is an easy way of quickly turning repositories on and off, which is useful when you desire a single package from a repository that you do not want to enable for updates or installs.

1 — include this repository as a package source.
```

Turning repositories on and off can also be performed quickly by passing either the `--enablerepo=<repo_name>` or `--disablerepo=<repo_name>` option to `yum`, or easily through PackageKit’s Add/Remove Software window.

Many more `[repository]` options exist. Refer to the `[repository] OPTIONS` section of `man yum.conf` for the exhaustive list and descriptions for each.

### 1.3.3. Using Yum Variables

You can use and reference the following variables in `yum` commands and in all `Yum` configuration files (`/etc/yum.conf` and all `.repo` files in `/etc/yum.repos.d/`).

**$releasever**

You can use this variable to reference the release version of Red Hat Enterprise Linux. `Yum` obtains the value of `$releasever` from the `distroverpkg=<value>` line in the `/etc/yum.conf` configuration file. If there is no such line in `/etc/yum.conf`, then `yum` infers the correct value by deriving the version number from the `redhat-release` package.

**$arch**

You can use this variable to refer to the system’s CPU architecture as returned when calling Python’s `os.uname()` function. Valid values for `$arch` include: `i586`, `i686` and `x86_64`.

**$basearch**

You can use `$basearch` to reference the base architecture of the system. For example, i686 and i586 machines both have a base architecture of `i386`, and AMD64 and Intel64 machines have a base architecture of `x86_64`.

**$YUM0-9**

These ten variables are each replaced with the value of any shell environment variables with the same name. If one of these variables is referenced (in `/etc/yum.conf` for example) and a shell environment variable with the same name does not exist, then the configuration file variable is not replaced.

### 1.3.4. Creating a Yum Repository

To set up a `Yum` repository, follow these steps:
Procedure 1.1. Setting Up a Yum repository

1. Install the createrepo package:

   ```
   ~# yum install createrepo
   ```

2. Copy all of the packages into one directory, such as `/mnt/local_repo/`.

3. Run the `createrepo --database` command on that directory:

   ```
   ~# createrepo --database /mnt/local_repo
   ```

**Important**

Because RPM packages for Red Hat Enterprise Linux 6 are compressed using the XZ lossless data compression format, and may also be signed using alternative (and stronger) hash algorithms such as SHA-256, it is not possible to run `createrepo` on Red Hat Enterprise Linux 5 to create the package metadata for Red Hat Enterprise Linux 6 packages. The `createrepo` command relies on `rpm` to open and inspect the packages, and `rpm` on Red Hat Enterprise Linux 5 is not able to open the improved Red Hat Enterprise Linux 6 RPM package format.

This will create the necessary metadata for your Yum repository, as well as the sqlite database for speeding up yum operations.

1.4. Yum Plugins

Yum provides plugins that extend and enhance its operations. Certain plugins are installed by default. Yum always informs you which plugins, if any, are loaded and active whenever you call any yum command:

```
~# yum info yum
Loaded plugins: presto, refresh-packagekit, security
[output truncated]
```

Note that the plugin names which follow Loaded plugins are the names you can provide to the --disableplugins=<plugin_name> option.

1.4.1. Enabling, Configuring and Disabling Yum Plugins

To enable Yum plugins, ensure that a line beginning with plugins= is present in the [main] section of `/etc/yum.conf`, and that its value is set to 1:

```
plugins=1
```

You can disable all plugins by changing this line to plugins=0.
Disabling plugins is not advised

Disabling all plugins is not advised because certain plugins provide important Yum services. In particular, rhnplugin enables connecting to Red Hat Network, and the security plugin allows system administrators to easily update the system with (sometimes critical) security updates. Disabling plugins globally is provided as a convenience option, and is generally only recommended when diagnosing a potential problem with Yum.

Every installed plugin has its own configuration file in the /etc/yum/pluginconf.d/ directory. You can set plugin-specific options in these files. For example, here is the security plugin's security.conf configuration file:

Example 1.7. A minimal Yum plugin configuration file

```
[main]
enabled=1
```

Plugin configuration files always contain a [main] section (similar to Yum's /etc/yum.conf file) in which there is (or you can place if it is missing) an enabled= option that controls whether the plugin is enabled when you run yum commands.

If you disable all plugins by setting enabled=0 in /etc/yum.conf, then all plugins are disabled regardless of whether they are enabled in their individual configuration files.

If you merely want to disable all Yum plugins for a single yum command, use the --noplugins option.

If you simply want to disable one or more Yum plugins for a single yum command, then you can add the --disableplugin=<plugin_name> option to the command:

Example 1.8. Disabling the presto plugin while running yum update

```
~# yum update --disableplugin=presto
```

The plugin names you provide to the --disableplugin= option are the same names listed after the Loaded plugins: line in the output of any yum command. You can disable multiple plugins by separating their names with commas. In addition, you can match multiple similarly-named plugin names or simply shorten long ones by using glob expressions: --disableplugin=presto,refresh-pack*.

1.4.2. Installing More Yum Plugins

Yum plugins usually adhere to the yum-plugin-<plugin_name> package-naming convention, but not always: the package which provides the presto plugin is named yum-presto, for example. You can install a Yum plugin in the same way you install other packages:

```
~# yum install yum-plugin-security
```
1.4.3. Plugin Descriptions
Here are descriptions of a few useful Yum plugins:

presto (yum-presto)
The presto plugin adds support to Yum for downloading delta RPM packages, during updates, from repositories which have presto metadata enabled. Delta RPMs contain only the differences between the version of the package installed on the client requesting the RPM package and the updated version in the repository. Downloading a delta RPM is much quicker than downloading the entire updated package, and can speed up updates considerably. Once the delta RPMs are downloaded, they must be rebuilt (the difference applied to the currently-installed package to create the full updated package) on the installing machine, which takes CPU time. Using delta RPMs is therefore a tradeoff between time-to-download, which depends on the network connection, and time-to-rebuild, which is CPU-bound. Using the presto plugin is recommended for fast machines and systems with slower network connections, while slower machines on very fast connections may benefit more from downloading normal RPM packages, i.e. by disabling presto. The presto plugin is enabled by default.

protect-packages (yum-plugin-protect-packages)
The protect-packages plugin prevents the yum package and all packages it depends on from being purposefully or accidentally removed. This simple scheme prevents many of the most important packages necessary for your system to run from being removed. In addition, you can list more packages, one per line, in the /etc/sysconfig/protected-packages file1 (which you should create if it does not exist), and protect-packages will extend protection-from-removal to those packages as well. To temporarily override package protection, use the --override-protection option with an applicable yum command.

rhnplugin (yum-rhn-plugin)
The rhnplugin for Yum provides support for connecting to Red Hat Network (RHN). Systems registered with RHN are able to update and install packages from Red Hat Network.

Refer to man rhnplugin for more information.

refresh-packagekit (PackageKit-yum-plugin)
This plugin updates metadata for PackageKit whenever yum is run. The refresh-packagekit plugin is installed by default.

security (yum-plugin-security)
Discovering information about and applying security updates easily and often is important to all system administrators. For this reason Yum provides the security plugin, which extends yum with a set of highly-useful security-related commands, subcommands and options.

You can check for all security-related updates as follows:

```
$ yum check-update --security
Loaded plugins: presto, refresh-packagekit, security
```

1 You can also place files with the extension .list in the /etc/sysconfig/protected-packages.d/ directory (which you should create if it does not exist), and list packages—one per line—in these files. protect-packages will protect these too.
Limiting package lists to security relevant ones

<table>
<thead>
<tr>
<th>Package</th>
<th>Version</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>elinks.x86_64</td>
<td>0.12-0.13.el6</td>
<td>rhel</td>
</tr>
<tr>
<td>kernel.x86_64</td>
<td>2.6.30.8-64.el6</td>
<td>rhel</td>
</tr>
<tr>
<td>kernel-headers.x86_64</td>
<td>2.6.30.8-64.el6</td>
<td>rhel</td>
</tr>
</tbody>
</table>

You can then use either `yum update --security` or `yum update-minimal --security` to update those packages which are affected by security advisories. Both of these commands update all packages on the system for which a security advisory has been issued. `yum update-minimal --security` updates them to the latest packages which were released as part of a security advisory, while `yum update --security` will update all packages affected by a security advisory to the latest version of that package available.

In other words, if:

- the `kernel-2.6.30.8-16` package is installed on your system;
- the `kernel-2.6.30.8-32` package was released as a security update;
- then `kernel-2.6.30.8-64` was released as a bug fix update,

...then `yum update-minimal --security` will update you to `kernel-2.6.30.8-32`, and `yum update --security` will update you to `kernel-2.6.30.8-64`. Conservative system administrators may want to use `update-minimal` to reduce the risk incurred by updating packages as much as possible.

Refer to `man yum-security` for usage details and further explanation of the enhancements the `security` plugin adds to `yum`.

### 1.5. Additional Resources

A useful resource that provides additional information about using the *Yum* package manager.
PackageKit

Red Hat provides PackageKit for viewing, managing, updating, installing and uninstalling packages compatible with your system. PackageKit consists of several graphical interfaces that can be opened from the GNOME panel menu, or from the Notification Area when PackageKit alerts you that updates are available. For more information on PackageKit's architecture and available front ends, refer to Section 2.3, "PackageKit Architecture".

2.1. Updating Packages with Software Update

PackageKit displays a starburst icon in the Notification Area whenever updates are available to be installed on your system.

Clicking on the notification icon opens the Software Update window. Alternatively, you can open Software Updates by clicking System → Administration → Software Update from the GNOME panel, or running the gpk-update-viewer command at the shell prompt. In the Software Updates window, all available updates are listed along with the names of the packages being updated (minus the .rpm suffix, but including the CPU architecture), a short summary of the package, and, usually, short descriptions of the changes the update provides. Any updates you do not wish to install can be de-selected here by unchecking the checkbox corresponding to the update.
There are 9 updates available

Software updates correct errors, eliminate security vulnerabilities and provide new features.

<table>
<thead>
<tr>
<th>Install</th>
<th>Software</th>
<th>Status</th>
<th>Size</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

The developer logs will be shown as no description is available for this update:

**2009-09-30** Dave Airlie <airlied@redhat.com> 2.6.31.1-56
- revert all the arjan patches until someone tests them.

**2009-09-29** Dave Airlie <airlied@redhat.com> 2.6.31.1-56
- drm-next-4c57edba4.patch: fix r600 dri memory leak and r600 bugs

9 updates selected (25.5 MB)

Figure 2.1. Installing updates with Software Update

The updates presented in the **Software Updates** window only represent the currently-installed packages on your system for which updates are available; dependencies of those packages, whether they are existing packages on your system or new ones, are not shown until you click **Install Updates**.

**PackageKit**
utilizes the fine-grained user authentication capabilities provided by the **PolicyKit** toolkit whenever you request it to make changes to the system. Whenever you instruct **PackageKit** to update, install or remove packages, you will be prompted to enter the superuser password before changes are made to the system.
Authentication is required to change software source parameters

An application is attempting to perform an action that requires privileges. Authentication as the super user is required to perform this action.

Password for root:

Details

Cancel Authenticate

Figure 2.2. PackageKit uses PolicyKit to authenticate

If you instruct PackageKit to update the kernel package, then it will prompt you after installation, asking you whether you want to reboot the system and thereby boot into the newly-installed kernel.

Setting the Update-Checking Interval

Right-clicking on PackageKit’s Notification Area icon and clicking Preferences opens the Software Update Preferences window, where you can define the interval at which PackageKit checks for package updates, as well as whether or not to automatically install all updates or only security updates, and how often to check for major upgrades. Leaving the Check for updates when using mobile broadband box unchecked is handy for avoiding extraneous bandwidth usage when using a wireless connection on which you are charged for the amount of data you download.

Figure 2.3. Setting PackageKit’s update-checking interval

2.2. Using Add/Remove Software

PackageKit’s Software Update GUI window is a separate application from its Add/Remove Software application, although the two have intuitively similar interfaces. To find and install a new package, on the GNOME panel click on System → Administration → Add/Remove Software, or run the gpk-application command at the shell prompt.
2.2.1. Refreshing Software Sources (Yum Repositories)

PackageKit refers to Yum repositories as software sources. It obtains all packages from enabled software sources. You can view the list of all configured and unfiltered (see below) Yum repositories by opening Add/Remove Software and clicking System → Software sources. The Software Sources dialog shows the repository name, as written on the name=<My Repository Name> field of all [repository] sections in the /etc/yum.conf configuration file, and in all repository.repo files in the /etc/yum.repos.d/ directory.

Entries which are checked in the Enabled column indicate that the corresponding repository will be used to locate packages to satisfy all update and installation requests (including dependency resolution). The Enabled column corresponds to the enabled=<1 or 0> field in [repository] sections. Checking an unchecked box enables the Yum repository, and unchecking it disables it. Performing either function causes PolicyKit to prompt for superuser authentication to enable or disable the repository. PackageKit actually inserts the enabled=<1 or 0> line into the correct [repository] section if it does not exist, or changes the value if it does. This means that enabling or disabling a repository through the Software Sources window causes that change to persist after closing the window or rebooting the system. The ability to quickly enable and disable repositories based on our needs is a highly-convenient feature of PackageKit.

Note that it is not possible to add or remove Yum repositories through PackageKit.

Showing Source RPM, Test and Debuginfo Repositories

Checking the box at the bottom of the Software Sources window causes PackageKit to display source RPM, testing and debuginfo repositories as well. This box is unchecked by default.

After enabling and/or disabling the correct Yum repositories, ensure that you have the latest list of available packages. Click on System → Refresh package lists and PackageKit will obtain the latest lists of packages from all enabled software sources, i.e. Yum repositories.
2.2.2. Finding Packages with Filters

Once the software sources have been updated, it is often beneficial to apply some filters so that PackageKit retrieves the results of our Find queries faster. This is especially helpful when performing many package searches. Four of the filters in the Filters drop-down menu are used to split results by matching or not matching a single criterion. By default when PackageKit starts, these filters are all unapplied (No filter), but once you do filter by one of them, that filter remains set until you either change it or close PackageKit.

Because you are usually searching for available packages that are not installed on the system, click Filters → Installed and select the Only available radio button.

Figure 2.5. Filtering out already-installed packages

Also, unless we require development files such as C header files, we can filter for Only end user files and, in doing so, filter out all of the `<package_name>-devel` packages we are not interested in.

Figure 2.6. Filtering out development packages from the list of Find results
Chapter 2. PackageKit

The two remaining filters with submenus are:

Graphical

Narrows the search to either applications which provide a GUI interface or those that do not (Only text). This filter is useful when browsing for GUI applications that perform a specific function.

Free

Search for packages which are considered to be free software Refer to the Fedora Licensing List\(^1\) for details on approved licenses.

The remaining checkbox filters are always either checked or unchecked. They are:

Hide subpackages

Checking the Hide subpackages checkbox filters out generally-uninteresting packages that are typically only dependencies of other packages that we want. For example, checking Hide subpackages and searching for \(<\text{package}\>\) would cause the following related packages to be filtered out of the Find results (if it exists):

- \(<\text{package}\>-\text{devel}\>
- \(<\text{package}\>-\text{libs}\>
- \(<\text{package}\>-\text{libs-devel}\>
- \(<\text{package}\>-\text{debuginfo}\>

Only newest items

Checking Only newest items filters out all older versions of the same package from the list of results, which is generally what we want.

Important: Using the Only newest items filter

Checking Only newest items filters out all but the most recent version of any package from the results list. This filter is often combined with the Only available filter to search for the latest available versions of new (not installed) packages.

Only native packages

Checking the Only native packages box on a multilib system causes PackageKit to omit listing results for packages compiled for the architecture that runs in compatibility mode. For example, enabling this filter on a 64-bit system with an AMD64 CPU would cause all packages built for the 32-bit x86 CPU architecture not to be shown in the list of results, even though those packages are able to run on an AMD64 machine. Packages which are architecture-agnostic (i.e. noarch packages such as \(\text{crontabs-1.10-32.1.e16.noarch.rpm}\)) are never filtered out by checking Only native packages. This filter has no affect on non-multilib systems, such as x86 machines.

---

\(^1\) https://fedoraproject.org/wiki/Licensing#SoftwareLicenses
2.2.3. Installing and Removing Packages (and Dependencies)

With the two filters selected, **Only available** and **Only end user files**, search for the `htop` interactive process viewer and highlight the package. You now have access to some very useful information about it, including: a clickable link to the project homepage; the **Yum** package group it is found in, if any; the license of the package; a pointer to the GNOME menu location from where the application can be opened, if applicable (**Applications → System Tools → Htop** in our case); and the size of the package, which is relevant when we download and install it.

![Figure 2.7. Viewing and installing a package with PackageKit's Add/Remove Software window](image)

When the checkbox next to a package or group is checked, then that item is already installed on the system. Checking an unchecked box causes it to be **marked** for installation, which only occurs when the **Apply** button is clicked. In this way, you can search for and select multiple packages or package groups before performing the actual installation transactions. Additionally, you can remove installed packages by unchecking the checked box, and the removal will occur along with any pending installations when **Apply** is pressed. Dependency resolution, which may add additional packages to be installed or removed, is performed after pressing **Apply**. **PackageKit** will then display a window listing those additional packages to install or remove, and ask for confirmation to proceed.

Check `htop` and click the **Apply** button. You will then be prompted for the superuser password; enter it, and **PackageKit** will install `htop`. One nice feature of **PackageKit** is that, following installation, it sometimes presents you with a list of your newly-installed applications and offers you the choice of running them immediately. Alternatively, you will remember that finding a package and selecting it in the **Add/Remove Software** window shows you the **Location** of where in the GNOME menus its application shortcut is located, which is helpful when you want to run it.

Once it is installed, you can run `htop`, an colorful and enhanced version of the `top` process viewer, by opening a shell prompt and entering:

```
$ htop
```
htop is nifty, but we decide that top is good enough for us and we want to uninstall it. Remembering that we need to change the Only available filter we recently used to install it to Only installed in Filters → Installed, we search for htop again and uncheck it. The program did not install any dependencies of its own; if it had, those would be automatically removed as well, as long as they were not also dependencies of any other packages still installed on our system.

Warning: Removing a Package when Other Packages Depend On It

Although PackageKit automatically resolves dependencies during package installation and removal, it is unable to remove a package without also removing packages which depend on it. This type of operation can only be performed by RPM, is not advised, and can potentially leave your system in a non-functioning state or cause applications to misbehave and/or crash.

Figure 2.8. Removing a package with PackageKit’s Add/Remove Software window
2.2.4. Installing and Removing Package Groups

PackageKit also has the ability to install Yum package groups, which it calls Package collections. Clicking on Package collections in the top-left list of categories in the Software Updates window allows us to scroll through and find the package group we want to install. In this case, we want to install Czech language support (the Czech Support group). Checking the box and clicking apply informs us how many additional packages must be installed in order to fulfill the dependencies of the package group.

![Figure 2.9. Installing the Czech Support package group](image)

Similarly, installed package groups can be uninstalled by selecting Package collections, unchecking the appropriate checkbox, and applying.

2.2.5. Viewing the Transaction Log

PackageKit maintains a log of the transactions that it performs. To view the log, from the Add/Remove Software window, click System → Software log, or run the gpk-log command at the shell prompt.

The Software Log Viewer shows the Action, such as Updated System or Installed Packages, the Date on which that action was performed, the Username of the user who performed the action, and the front end Application the user used (such as Update Icon, or kpackagekit). The Details column provides the types of the transactions, such as Updated, Installed or Removed, as well as the list of packages the transactions were performed on.
Figure 2.10. Viewing the log of package management transactions with the Software Log Viewer

Typing the name of a package in the top text entry field filters the list of transactions to those which affected that package.

2.3. PackageKit Architecture

Red Hat provides the PackageKit suite of applications for viewing, updating, installing and uninstalling packages and package groups compatible with your system. Architecturally, PackageKit consists of several graphical front ends that communicate with the packagekitd daemon back end, which communicates with a package manager-specific back end that utilizes Yum to perform the actual transactions, such as installing and removing packages, etc.

Table 2.1, “PackageKit GUI Windows, Menu Locations, and Shell Prompt Commands” shows the name of the GUI window, how to start the window from the GNOME desktop or from the Add/Remove Software window, and the name of the command line application that opens that window.

<table>

</table>
The `packagekitd` daemon runs outside the user session and communicates with the various graphical front ends. The `packagekitd` daemon\(^2\) communicates via the `DBus` system message bus with another back end, which utilizes `Yum`'s Python API to perform queries and make changes to the system. On Linux systems other than Red Hat and Fedora, `packagekitd` can communicate with other back ends that are able to utilize the native package manager for that system. This modular architecture provides the abstraction necessary for the graphical interfaces to work with many different package managers to perform essentially the same types of package management tasks. Learning how to use the `PackageKit` front ends means that you can use the same familiar graphical interface across many different Linux distributions, even when they utilize a native package manager other than `Yum`.

In addition, `PackageKit`'s separation of concerns provides reliability in that a crash of one of the GUI windows—or even the user's X Window session—will not affect any package management tasks being supervised by the `packagekitd` daemon, which runs outside of the user session.

All of the front end graphical applications discussed in this chapter are provided by the `gnome-packagekit` package instead of by `PackageKit` and its dependencies. Users working in a KDE environment may prefer to install the `kpackagekit` package, which provides a KDE interface for `PackageKit`.

Finally, `PackageKit` also comes with a console-based frontend called `pkcon`.

---

\(^2\) System daemons are typically long-running processes that provide services to the user or to other programs, and which are started, often at boot time, by special initialization scripts (often shortened to `init scripts`). Daemons respond to the `service` command and can be turned on or off permanently by using the `chkconfig on` or `chkconfig off` commands. They can typically be recognized by a “d” appended to their name, such as the `packagekitd` daemon. Refer to Chapter 7, *Controlling Access to Services* for information about system services.
The RPM Package Manager (RPM) is an open packaging system, which runs on Red Hat Enterprise Linux as well as other Linux and UNIX systems. Red Hat, Inc. and the Fedora Project encourage other vendors to use RPM for their own products. RPM is distributed under the terms of the GPL (GNU General Public License).

The RPM Package Manager only works with packages built to work with the RPM format. RPM is itself provided as a pre-installed rpm package. For the end user, RPM makes system updates easy. Installing, uninstalling and upgrading RPM packages can be accomplished with short commands. RPM maintains a database of installed packages and their files, so you can invoke powerful queries and verifications on your system.

The RPM package format has been improved for Red Hat Enterprise Linux 6. RPM packages are now compressed using the XZ lossless data compression format, which has the benefit of greater compression and less CPU usage during decompression, and support multiple strong hash algorithms, such as SHA-256, for package signing and verification.

Use Yum Instead of RPM Whenever Possible

For most package management tasks, the Yum package manager offers equal and often greater capabilities and utility than RPM. Yum also performs and tracks complicated system dependency resolution, and will complain and force system integrity checks if you use RPM as well to install and remove packages. For these reasons, it is highly recommended that you use Yum instead of RPM whenever possible to perform package management tasks. Refer to Chapter 1, Yum.

If you prefer a graphical interface, you can use the PackageKit GUI application, which uses Yum as its back end, to manage your system’s packages. Refer to Chapter 2, PackageKit for details.

Important

When installing a package, ensure it is compatible with your operating system and processor architecture. This can usually be determined by checking the package name. Many of the following examples show RPM packages compiled for the AMD64/Intel 64 computer architectures; thus, the RPM file name ends in x86_64.rpm.

During upgrades, RPM handles configuration files carefully, so that you never lose your customizations—something that you cannot accomplish with regular .tar.gz files.

For the developer, RPM allows you to take software source code and package it into source and binary packages for end users. This process is quite simple and is driven from a single file and optional patches that you create. This clear delineation between pristine sources and your patches along with build instructions eases the maintenance of the package as new versions of the software are released.
Chapter 3. RPM

3.1. RPM Design Goals
To understand how to use RPM, it can be helpful to understand the design goals of RPM:

Upgradability

With RPM, you can upgrade individual components of your system without completely reinstalling. When you get a new release of an operating system based on RPM, such as Red Hat Enterprise Linux, you do not need to reinstall a fresh copy of the operating system your machine (as you might need to with operating systems based on other packaging systems). RPM allows intelligent, fully-automated, in-place upgrades of your system. In addition, configuration files in packages are preserved across upgrades, so you do not lose your customizations. There are no special upgrade files needed to upgrade a package because the same RPM file is used to both install and upgrade the package on your system.

Powerful Querying

RPM is designed to provide powerful querying options. You can perform searches on your entire database for packages or even just certain files. You can also easily find out what package a file belongs to and from where the package came. The files an RPM package contains are in a compressed archive, with a custom binary header containing useful information about the package and its contents, allowing you to query individual packages quickly and easily.

System Verification

Another powerful RPM feature is the ability to verify packages. If you are worried that you deleted an important file for some package, you can verify the package. You are then notified of anomalies, if any—at which point you can reinstall the package, if necessary. Any configuration files that you modified are preserved during reinstallation.

Pristine Sources

A crucial design goal was to allow the use of pristine software sources, as distributed by the original authors of the software. With RPM, you have the pristine sources along with any patches that were used, plus complete build instructions. This is an important advantage for several reasons. For instance, if a new version of a program is released, you do not necessarily have to start from scratch to get it to compile. You can look at the patch to see what you might need to do. All the compiled-in defaults, and all of the changes that were made to get the software to build properly, are easily visible using this technique.

The goal of keeping sources pristine may seem important only for developers, but it results in higher quality software for end users, too.

3.2. Using RPM
RPM has five basic modes of operation
Finding RPM Packages

3.2.1. Finding RPM Packages

Before using any RPM packages, you must know where to find them. An Internet search returns many RPM repositories, but if you are looking for Red Hat RPM packages, they can be found at the following locations:

- The Red Hat Enterprise Linux installation media contain many installable RPMs.
- The initial RPM repositories provided with the YUM package manager. Refer to Chapter 1, Yum for details on how to use the official Red Hat Enterprise Linux package repositories.
- The Extra Packages for Enterprise Linux (EPEL) is a community effort to provide high-quality add-on packages for Red Hat Enterprise Linux. Refer to http://fedoraproject.org/wiki/EPEL for details on EPEL RPM packages.
- Unofficial, third-party repositories not affiliated with Red Hat also provide RPM packages.

**Important**

When considering third-party repositories for use with your Red Hat Enterprise Linux system, pay close attention to the repository's web site with regard to package compatibility before adding the repository as a package source. Alternate package repositories may offer different, incompatible versions of the same software, including packages already included in the Red Hat Enterprise Linux repositories.

3.2.2. Installing and Upgrading

RPM packages typically have file names like `tree-1.5.3-2.el6.x86_64.rpm`. The file name includes the package name (`tree`), version (1.5.3), release (2), operating system major version (`el6`) and CPU architecture (`x86_64`).

You can use `rpm`'s `-U` option to:

- upgrade an existing but older package on the system to a newer version, or
- install the package even if an older version is not already installed.

That is, `rpm -U <rpm_file>` is able to perform the function of either upgrading or installing as is appropriate for the package.

Assuming the `tree-1.5.3-2.el6.x86_64.rpm` package is in the current directory, log in as root and type the following command at a shell prompt to either upgrade or install the `tree` package as determined by `rpm`: 

---

(not counting package building): installing, uninstalling, upgrading, querying, and verifying. This section contains an overview of each mode. For complete details and options, try `rpm --help` or `man rpm`. You can also refer to Section 3.5, “Additional Resources” for more information on RPM.
Chapter 3. RPM

rpm -Uvh tree-1.5.3-2.el6.x86_64.rpm

Use -Uvh for nicely-formatted RPM installs

The -v and -h options (which are combined with -U) cause rpm to print more verbose output and display a progress meter using hash signs.

If the upgrade/installation is successful, the following output is displayed:

Preparing...                ########################################### [100%]
1:tree                   ########################################### [100%]

Always use the -i (install) option to install new kernel packages!

rpm provides two different options for installing packages: the aforementioned -U option (which historically stands for upgrade), and the -i option, historically standing for install. Because the -U option subsumes both install and upgrade functions, we recommend to use rpm -Uvh with all packages except kernel packages.

You should always use the -i option to simply install a new kernel package instead of upgrading it. This is because using the -U option to upgrade a kernel package removes the previous (older) kernel package, which could render the system unable to boot if there is a problem with the new kernel. Therefore, use the rpm -i <kernel_package> command to install a new kernel without replacing any older kernel packages. For more information on installing kernel packages, refer to Chapter 23, Manually Upgrading the Kernel.

The signature of a package is checked automatically when installing or upgrading a package. The signature confirms that the package was signed by an authorized party. For example, if the verification of the signature fails, an error message such as the following is displayed:

error: tree-1.5.3-2.el6.x86_64.rpm: Header V3 RSA/SHA256 signature: BAD, key ID d22e77f2

If it is a new, header-only, signature, an error message such as the following is displayed:

error: tree-1.5.3-2.el6.x86_64.rpm: Header V3 RSA/SHA256 signature: BAD, key ID d22e77f2

If you do not have the appropriate key installed to verify the signature, the message contains the word NOKEY:

warning: tree-1.5.3-2.el6.x86_64.rpm: Header V3 RSA/SHA1 signature: NOKEY, key ID 57bbccba

Refer to Section 3.3, “Checking a Package’s Signature” for more information on checking a package’s signature.

3.2.2.1. Package Already Installed

If a package of the same name and version is already installed
Installing and Upgrading

, the following output is displayed:

```
Preparing... #xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx [100%]
package tree-1.5.3-2.el6.x86_64 is already installed
```

However, if you want to install the package anyway, you can use the `--replacepkgs` option, which tells RPM to ignore the error:

```
rpm -Uvh --replacepkgs tree-1.5.3-2.el6.x86_64.rpm
```

This option is helpful if files installed from the RPM were deleted or if you want the original configuration files from the RPM to be installed.

### 3.2.2.2. Conflicting Files

If you attempt to install a package that contains a file which has already been installed by another package, the following is displayed:

```
Preparing... #xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
file /usr/bin/foobar from install of foo-1.0-1.el6.x86_64 conflicts
with file from package bar-3.1.1.el6.x86_64
```

To make RPM ignore this error, use the `--replacefiles` option:

```
rpm -Uvh --replacefiles foo-1.0-1.el6.x86_64.rpm
```

### 3.2.2.3. Unresolved Dependency

RPM packages may sometimes depend on other packages, which means that they require other packages to be installed to run properly. If you try to install a package which has an unresolved dependency, output similar to the following is displayed:

```
error: Failed dependencies:
  bar.so.3()(64bit) is needed by foo-1.0-1.el6.x86_64
```

If you are installing a package from the Red Hat Enterprise Linux installation media, such as from a CD-ROM or DVD, the dependencies may be available. Find the suggested package(s) on the Red Hat Enterprise Linux installation media or on one of the active Red Hat Enterprise Linux mirrors and add it to the command:

```
rpm -Uvh foo-1.0-1.el6.x86_64.rpm    bar-3.1.1.el6.x86_64.rpm
```

If installation of both packages is successful, output similar to the following is displayed:

```
Preparing... #xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx [100%]
1:foo #xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx [ 50%]
2:bar #xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx [100%]
```

You can try the `--whatprovides` option to determine which package contains the required file.
rpm -q --whatprovides "bar.so.3"

If the package that contains `bar.so.3` is in the RPM database, the name of the package is displayed:

```
bar-3.1.1.el6.i586.rpm
```

**Warning: Forcing Package Installation**

Although we can force `rpm` to install a package that gives us a `Failed dependencies` error (using the `--nodeps` option), this is not recommended, and will usually result in the installed package failing to run. Installing or removing packages with `rpm --nodeps` can cause applications to misbehave and/or crash, and can cause serious package management problems or, possibly, system failure. For these reasons, it is best to heed such warnings; the package manager—whether `RPM`, `Yum` or `PackageKit`—shows us these warnings and suggests possible fixes because accounting for dependencies is critical. The `Yum` package manager can perform dependency resolution and fetch dependencies from online repositories, making it safer, easier and smarter than forcing `rpm` to carry out actions without regard to resolving dependencies.

### 3.2.3. Configuration File Changes

Because RPM performs intelligent upgrading of packages with configuration files, you may see one or the other of the following messages:

```
saving /etc/foo.conf as /etc/foo.conf.rpmsave
```

This message means that changes you made to the configuration file may not be `forward-compatible` with the new configuration file in the package, so RPM saved your original file and installed a new one. You should investigate the differences between the two configuration files and resolve them as soon as possible, to ensure that your system continues to function properly.

Alternatively, RPM may save the package's new configuration file as, for example, `foo.conf.rpmnew`, and leave the configuration file you modified untouched. You should still resolve any conflicts between your modified configuration file and the new one, usually by merging changes from the old one to the new one with a `diff` program.

If you attempt to upgrade to a package with an _older_ version number (that is, if a higher version of the package is already installed), the output is similar to the following:

```
package foo-2.0-1.el6.x86_64.rpm (which is newer than foo-1.0-1) is already installed
```

To force RPM to upgrade anyway, use the `--oldpackage` option:

```
rpm -Uvh --oldpackage foo-1.0-1.el6.x86_64.rpm
```

### 3.2.4. Uninstalling

Uninstalling a package is just as simple as installing one. Type the following command at a shell prompt:
Note

Notice that we used the package name `foo`, not the name of the original package file, `foo-1.0-1.el6.x86_64`. If you attempt to uninstall a package using the `rpm -e` command and the original full file name, you will receive a package name error.

You can encounter dependency errors when uninstalling a package if another installed package depends on the one you are trying to remove. For example:

```bash
rpm -e ghostscript
error: Failed dependencies:
  libgs.so.8()(64bit) is needed by (installed) libspectre-0.2.2.3.el6.x86_64
  libgs.so.8()(64bit) is needed by (installed) foomatic-4.0.3-1.el6.x86_64
  libijs-0.35.so()(64bit) is needed by (installed) gutenprint-5.2.4-5.el6.x86_64
  ghostscript is needed by (installed) printer-filters-1.1-4.el6.noarch
```

Similar to how we searched for a shared object library (i.e. a `<library_name>.so.<number>` file) in Section 3.2.2.3, "Unresolved Dependency", we can search for a 64-bit shared object library using this exact syntax (and making sure to quote the file name):

```bash
~]# rpm -q --whatprovides "libgs.so.8()(64bit)"
ghostscript-8.70-1.el6.x86_64
```

Warning: Forcing Package Installation

Although we can force `rpm` to remove a package that gives us a Failed dependencies error (using the `-nodeps` option), this is not recommended, and may cause harm to other installed applications. Installing or removing packages with `rpm -nodeps` can cause applications to misbehave and/or crash, and can cause serious package management problems or, possibly, system failure. For these reasons, it is best to heed such warnings; the package manager—whether `RPM`, `Yum` or `PackageKit`—shows us these warnings and suggests possible fixes because accounting for dependencies is critical. The Yum package manager can perform dependency resolution and fetch dependencies from online repositories, making it safer, easier and smarter than forcing `rpm` to carry out actions without regard to resolving dependencies.

3.2.5. Freshening

Freshening is similar to upgrading, except that only existent packages are upgraded. Type the following command at a shell prompt:

```bash
rpm -Fvh foo-2.0-1.el6.x86_64.rpm
```

RPM's freshen option checks the versions of the packages specified on the command line against the versions of packages that have already been installed on your system. When a newer version of an already-installed package is processed by RPM's freshen option, it is upgraded to the newer version. However, RPM's freshen option does not install a package if no previously-installed package of the
same name exists. This differs from RPM’s upgrade option, as an upgrade does install packages whether or not an older version of the package was already installed.

Freshening works for single packages or package groups. If you have just downloaded a large number of different packages, and you only want to upgrade those packages that are already installed on your system, freshening does the job. Thus, you do not have to delete any unwanted packages from the group that you downloaded before using RPM.

In this case, issue the following with the *.rpm glob:

```
rpm -Fvh *.rpm
```

RPM then automatically upgrades only those packages that are already installed.

### 3.2.6. Querying

The RPM database stores information about all RPM packages installed in your system. It is stored in the directory `/var/lib/rpm/`, and is used to query what packages are installed, what versions each package is, and to calculate any changes to any files in the package since installation, among other use cases.

To query this database, use the `-q` option. The `rpm -q package name` command displays the package name, version, and release number of the installed package `<package name>`. For example, using `rpm -q tree` to query installed package `tree` might generate the following output:

```
tree-1.5.2.2-4.el6.x86_64
```

You can also use the following `Package Selection Options` (which is a subheading in the RPM man page: see `man rpm` for details) to further refine or qualify your query:

- `-a` — queries all currently installed packages.
- `-f <file_name>` — queries the RPM database for which package owns `<file_name>`.
  Specify the absolute path of the file (for example, `rpm -qf /bin/ls` instead of `rpm -qf ls`).
- `-p <package_file>` — queries the uninstalled package `<package_file>`.

There are a number of ways to specify what information to display about queried packages. The following options are used to select the type of information for which you are searching. These are called the `Package Query Options`.

- `-i` displays package information including name, description, release, size, build date, install date, vendor, and other miscellaneous information.
- `-l` displays the list of files that the package contains.
- `-s` displays the state of all the files in the package.
- `-d` displays a list of files marked as documentation (man pages, info pages, READMEs, etc.) in the package.
- `-c` displays a list of files marked as configuration files. These are the files you edit after installation to adapt and customize the package to your system (for example, `sendmail.cf`, `passwd`, `inittab`, etc.).
Verifying

For options that display lists of files, add `-v` to the command to display the lists in a familiar `ls -l` format.

3.2.7. Verifying

Verifying a package compares information about files installed from a package with the same information from the original package. Among other things, verifying compares the file size, MD5 sum, permissions, type, owner, and group of each file.

The command `rpm -V` verifies a package. You can use any of the Verify Options listed for querying to specify the packages you wish to verify. A simple use of verifying is `rpm -V tree`, which verifies that all the files in the `tree` package are as they were when they were originally installed. For example:

- To verify a package containing a particular file:
  
  ```
  rpm -Vf /usr/bin/tree
  ```

  In this example, `/usr/bin/tree` is the absolute path to the file used to query a package.

- To verify ALL installed packages throughout the system (which will take some time):
  ```
  rpm -Va
  ```

- To verify an installed package against an RPM package file:
  ```
  rpm -Vp tree-1.5.3-2.el6.x86_64.rpm
  ```

  This command can be useful if you suspect that your RPM database is corrupt.

If everything verified properly, there is no output. If there are any discrepancies, they are displayed. The format of the output is a string of eight characters (a "c" denotes a configuration file) and then the file name. Each of the eight characters denotes the result of a comparison of one attribute of the file to the value of that attribute recorded in the RPM database. A single period (.) means the test passed. The following characters denote specific discrepancies:

- **5** — MD5 checksum
- **S** — file size
- **L** — symbolic link
- **T** — file modification time
- **D** — device
- **U** — user
- **G** — group
- **M** — mode (includes permissions and file type)
- **?** — unreadable file (file permission errors, for example)
If you see any output, use your best judgment to determine if you should remove the package, reinstall it, or fix the problem in another way.

3.3. Checking a Package's Signature

If you wish to verify that a package has not been corrupted or tampered with, examine only the md5sum by typing the following command at a shell prompt (where `<rpm_file>` is the file name of the RPM package):

```
rpm -K --nosignature <rpm_file>
```

The message `<rpm_file>`: rsa sha1 (md5) pgp md5 OK (specifically the OK part of it) is displayed. This brief message means that the file was not corrupted during download. To see a more verbose message, replace `-K` with `-Kvv` in the command.

On the other hand, how trustworthy is the developer who created the package? If the package is signed with the developer's GnuPG key, you know that the developer really is who they say they are.

An RPM package can be signed using Gnu Privacy Guard (or GnuPG), to help you make certain your downloaded package is trustworthy.

GnuPG is a tool for secure communication; it is a complete and free replacement for the encryption technology of PGP, an electronic privacy program. With GnuPG, you can authenticate the validity of documents and encrypt/decrypt data to and from other recipients. GnuPG is capable of decrypting and verifying PGP 5.x files as well.

During installation, GnuPG is installed by default. That way you can immediately start using GnuPG to verify any packages that you receive from Red Hat. Before doing so, you must first import Red Hat's public key.

3.3.1. Importing Keys

To verify Red Hat packages, you must import the Red Hat GPG key. To do so, execute the following command at a shell prompt:

```
rpm --import /usr/share/rhn/RPM-GPG-KEY
```

To display a list of all keys installed for RPM verification, execute the command:

```
rpm -qa gpg-pubkey*
```

For the Red Hat key, the output includes:

```
gpg-pubkey-db42a60e-37ea5438
```

To display details about a specific key, use `rpm -qi` followed by the output from the previous command:
3.3.2. Verifying Signature of Packages
To check the GnuPG signature of an RPM file after importing the builder’s GnuPG key, use the following command (replace `<rpm-file>` with the filename of the RPM package):

```
rpm -K <rpm-file>
```

If all goes well, the following message is displayed: **md5 gpg OK**. This means that the signature of the package has been verified, that it is not corrupt, and therefore is safe to install and use.

3.4. Practical and Common Examples of RPM Usage
RPM is a useful tool for both managing your system and diagnosing and fixing problems. The best way to make sense of all its options is to look at some examples.

• Perhaps you have deleted some files by accident, but you are not sure what you deleted. To verify your entire system and see what might be missing, you could try the following command:

```
rpm -Va
```

If some files are missing or appear to have been corrupted, you should probably either re-install the package or uninstall and then re-install the package.

• At some point, you might see a file that you do not recognize. To find out which package owns it, enter:

```
rpm -qf /usr/bin/ghostscript
```

The output would look like the following:

```
ghostscript-8.70-1.el6.x86_64
```

• We can combine the above two examples in the following scenario. Say you are having problems with `/usr/bin/paste`. You would like to verify the package that owns that program, but you do not know which package owns `paste`. Enter the following command,

```
rpm -Vf /usr/bin/paste
```

and the appropriate package is verified.

• Do you want to find out more information about a particular program? You can try the following command to locate the documentation which came with the package that owns that program:

```
rpm -qdf /usr/bin/free
```
Chapter 3. RPM

The output would be similar to the following:

```
/usr/share/doc/procps-3.2.8/BUGS
/usr/share/doc/procps-3.2.8/FAQ
/usr/share/doc/procps-3.2.8/NEWS
/usr/share/doc/procps-3.2.8/TODD
/usr/share/man/man1/free.1.gz
/usr/share/man/man1/pgrep.1.gz
/usr/share/man/man1/pkill.1.gz
/usr/share/man/man1/pmap.1.gz
/usr/share/man/man1/ps.1.gz
/usr/share/man/man1/pwdx.1.gz
/usr/share/man/man1/skill.1.gz
/usr/share/man/man1/slabtop.1.gz
/usr/share/man/man1/snice.1.gz
/usr/share/man/man1/tload.1.gz
/usr/share/man/man1/top.1.gz
/usr/share/man/man1/top.1.gz
/usr/share/man/man1/uptime.1.gz
/usr/share/man/man1/w.1.gz
/usr/share/man/man1/watch.1.gz
/usr/share/man/man5/sysctl.conf.5.gz
/usr/share/man/man8/vmstat.8.gz
```

- You may find a new RPM, but you do not know what it does. To find information about it, use the following command:

```
rpm -qip crontabs-1.10-32.1.el6.noarch.rpm
```

The output would be similar to the following:

```
Name        : crontabs                     Relocations: (not relocatable)
Version     : 1.10                              Vendor: Red Hat, Inc.
Release     : 32.1.el6                      Build Date: Thu 03 Dec 2009 02:17:44 AM CET
Install Date: (not installed)               Build Host: js20-bc1-11.build.redhat.com
Group       : System Environment/Base       Source RPM: crontabs-1.10-32.1.el6.src.rpm
Size        : 2486                             License: Public Domain and GPLv2
Signature   : RSA/8, Wed 24 Feb 2010 08:46:13 PM CET, Key ID 938a80caf21541eb
Summary     : Root crontab files used to schedule the execution of programs
Description :
The crontabs package contains root crontab files and directories.
You will need to install cron daemon to run the jobs from the crontabs.
The cron daemon such as cronie or fcron checks the crontab files to see when particular commands are scheduled to be executed. If commands are scheduled, it executes them.
Crontabs handles a basic system function, so it should be installed on your system.
```

- Perhaps you now want to see what files the `crontabs` RPM package installs. You would enter the following:

```
rpm -qlp crontabs-1.10-32.1.el6.noarch.rpm
```

The output is similar to the following:
These are just a few examples. As you use RPM, you may find more uses for it.

### 3.5. Additional Resources

RPM is an extremely complex utility with many options and methods for querying, installing, upgrading, and removing packages. Refer to the following resources to learn more about RPM.

#### 3.5.1. Installed Documentation

- **rpm --help** — This command displays a quick reference of RPM parameters.

- **man rpm** — The RPM man page gives more detail about RPM parameters than the `rpm --help` command.

#### 3.5.2. Useful Websites

- The RPM mailing list can be subscribed to, and its archives read from, here — [https://lists.rpm.org/mailman/listinfo/rpm-list](https://lists.rpm.org/mailman/listinfo/rpm-list)

#### 3.5.3. Related Books

*Maximum RPM* — [http://www.redhat.com/docs/books/max-rpm/](http://www.redhat.com/docs/books/max-rpm/)

The *Maximum RPM* book, which you can read online or download in HTML or PDF, covers everything from general RPM usage to building your own RPMs to programming with rpmlib.

The *Red Hat RPM Guide* by Eric Foster-Johnson is an excellent resource on all details of the RPM package format and the RPM package management utility.
Part II. Network-Related Configuration

After explaining how to configure the network, this part discusses topics related to networking such as how to allow remote logins, share files and directories over the network, and set up a Web server.
Network Interfaces

Under Red Hat Enterprise Linux, all network communications occur between configured software *interfaces* and *physical networking devices* connected to the system.

The configuration files for network interfaces are located in the `/etc/sysconfig/network-scripts/` directory. The scripts used to activate and deactivate these network interfaces are also located here. Although the number and type of interface files can differ from system to system, there are three categories of files that exist in this directory:

1. *Interface configuration files*
2. *Interface control scripts*
3. *Network function files*

The files in each of these categories work together to enable various network devices.

This chapter explores the relationship between these files and how they are used.

**4.1. Network Configuration Files**

Before delving into the interface configuration files, let us first itemize the primary configuration files used in network configuration. Understanding the role these files play in setting up the network stack can be helpful when customizing a Red Hat Enterprise Linux system.

The primary network configuration files are as follows:

/`etc/hosts`

The main purpose of this file is to resolve hostnames that cannot be resolved any other way. It can also be used to resolve hostnames on small networks with no DNS server. Regardless of the type of network the computer is on, this file should contain a line specifying the IP address of the loopback device (`127.0.0.1`) as `localhost.localdomain`. For more information, refer to the `hosts` man page.

/`etc/resolv.conf`

This file specifies the IP addresses of DNS servers and the search domain. Unless configured to do otherwise, the network initialization scripts populate this file. For more information about this file, refer to the `resolv.conf` man page.

/`etc/sysconfig/network`

This file specifies routing and host information for all network interfaces. For more information about this file and the directives it accepts, refer to *Section 18.1.13, “/etc/sysconfig/network”*.

/`etc/sysconfig/network-scripts/ifcfg-<interface-name>`

For each network interface, there is a corresponding interface configuration script. Each of these files provide information specific to a particular network interface. Refer to *Section 4.2, “Interface Configuration Files”* for more information on this type of file and the directives it accepts.
Chapter 4. Network Interfaces

4.2. Interface Configuration Files

Interface configuration files control the software interfaces for individual network devices. As the system boots, it uses these files to determine what interfaces to bring up and how to configure them. These files are usually named `ifcfg-<name>`, where `<name>` refers to the name of the device that the configuration file controls.

4.2.1. Ethernet Interfaces

One of the most common interface files is `ifcfg-eth0`, which controls the first Ethernet network interface card or NIC in the system. In a system with multiple NICs, there are multiple `ifcfg-eth<x>` files (where `<X>` is a unique number corresponding to a specific interface). Because each device has its own configuration file, an administrator can control how each interface functions individually.

The following is a sample `ifcfg-eth0` file for a system using a fixed IP address:

```
DEVICE=eth0
BOOTPROTO=none
ONBOOT=yes
NETMASK=255.255.255.0
IPADDR=10.0.1.27
USERCTL=no
```

The values required in an interface configuration file can change based on other values. For example, the `ifcfg-eth0` file for an interface using DHCP looks different because IP information is provided by the DHCP server:

```
DEVICE=eth0
BOOTPROTO=dhcp
ONBOOT=yes
```

The Network Administration Tool (`system-config-network`) is an easy way to make changes to the various network interface configuration files (refer to Chapter 5, Network Configuration for detailed instructions on using this tool).

However, it is also possible to manually edit the configuration files for a given network interface.

Below is a listing of the configurable parameters in an Ethernet interface configuration file:

- `BONDING_OPTS=<parameters>`
  - sets the configuration parameters for the bonding device, and is used in `/etc/sysconfig/network-scripts/ifcfg-bond<N>` (see Section 4.2.2, “Channel Bonding Interfaces”). These parameters are identical to those used for bonding devices in `/sys/class/net/<bonding device>/bonding`, and the module parameters for the bonding driver as described in `bonding Module Directives`. 

Warning

The `/etc/sysconfig/networking/` directory is used by the Network Administration Tool (`system-config-network`) and its contents should not be edited manually. Using only one method for network configuration is strongly encouraged, due to the risk of configuration deletion.

For more information about configuring network interfaces using the Network Administration Tool, refer to Chapter 5, Network Configuration.
This configuration method is used so that multiple bonding devices can have different configurations. It is highly recommended to place all of your bonding options after the BONDING_OPTS directive in ifcfg-<name>. Do not specify options for the bonding device in /etc/modprobe.d/<bonding>.conf, or in the deprecated /etc/modprobe.conf file.

BOOTPROTO=<protocol>
where <protocol> is one of the following:

- none — No boot-time protocol should be used.
- bootp — The BOOTP protocol should be used.
- dhcp — The DHCP protocol should be used.

BROADCAST=<address>
where <address> is the broadcast address. This directive is deprecated, as the value is calculated automatically with ifcalc.

DEVICE=<name>
where <name> is the name of the physical device (except for dynamically-allocated PPP devices where it is the logical name).

DHCP_HOSTNAME
Use this option only if the DHCP server requires the client to specify a hostname before receiving an IP address.

DNS{1,2}=<address>
where <address> is a name server address to be placed in /etc/resolv.conf if the PEERDNS directive is set to yes.

ETHTOOL_OPTS=<options>
where <options> are any device-specific options supported by ethtool. For example, if you wanted to force 100Mb, full duplex:

```
ETHTOOL_OPTS="autoneg off speed 100 duplex full"
```

Instead of a custom initscript, use ETHTOOL_OPTS to set the interface speed and duplex settings. Custom initscripts run outside of the network init script lead to unpredictable results during a post-boot network service restart.

**Note**

Changing speed or duplex settings almost always requires disabling autonegotiation with the autoneg off option. This needs to be stated first, as the option entries are order-dependent.

GATEWAY=<address>
where <address> is the IP address of the network router or gateway device (if any).

HWADDR=<MAC-address>
where <MAC-address> is the hardware address of the Ethernet device in the form AA:BB:CC:DD:EE:FF. This directive must be used in machines containing more than one NIC to
Chapter 4. Network Interfaces

ensure that the interfaces are assigned the correct device names regardless of the configured load order for each NIC's module. This directive should **not** be used in conjunction with **MACADDR**.

**IPADDR=**<address>
where <address> is the IP address.

**MACADDR=**<MAC-address>
where <MAC-address> is the hardware address of the Ethernet device in the form AA:BB:CC:DD:EE:FF. This directive is used to assign a MAC address to an interface, overriding the one assigned to the physical NIC. This directive should **not** be used in conjunction with **HWADDR**.

**MASTER=**<bond-interface>
where <bond-interface> is the channel bonding interface to which the Ethernet interface is linked.

This directive is used in conjunction with the **SLAVE** directive.

Refer to Section 4.2.2, “Channel Bonding Interfaces” for more information about channel bonding interfaces.

**NETMASK=**<mask>
where <mask> is the netmask value.

**NETWORK=**<address>
where <address> is the network address. This directive is deprecated, as the value is calculated automatically with **ifcalc**.

**ONBOOT=**<answer>
where <answer> is one of the following:

- **yes** — This device should be activated at boot-time.
- **no** — This device should not be activated at boot-time.

**PEERDNS=**<answer>
where <answer> is one of the following:

- **yes** — Modify /etc/resolv.conf if the DNS directive is set. If using DHCP, then **yes** is the default.
- **no** — Do not modify /etc/resolv.conf.

**SLAVE=**<answer>
where <answer> is one of the following:

- **yes** — This device is controlled by the channel bonding interface specified in the **MASTER** directive.
- **no** — This device is **not** controlled by the channel bonding interface specified in the **MASTER** directive.

This directive is used in conjunction with the **MASTER** directive.

Refer to Section 4.2.2, “Channel Bonding Interfaces” for more about channel bonding interfaces.

**SRCADDR=**<address>
where <address> is the specified source IP address for outgoing packets.
USERCTL=<answer>
where <answer> is one of the following:

- **yes** — Non-root users are allowed to control this device.
- **no** — Non-root users are not allowed to control this device.

### 4.2.2. Channel Bonding Interfaces

Red Hat Enterprise Linux allows administrators to bind multiple network interfaces together into a single channel using the **bonding** kernel module and a special network interface called a channel bonding interface. Channel bonding enables two or more network interfaces to act as one, simultaneously increasing the bandwidth and providing redundancy.

To create a channel bonding interface, create a file in the `/etc/sysconfig/network-scripts/` directory called `ifcfg-bond<N>`, replacing `<N>` with the number for the interface, such as `0`.

The contents of the file can be identical to whatever type of interface is getting bonded, such as an Ethernet interface. The only difference is that the `DEVICE=` directive must be `bond<N>`, replacing `<N>` with the number for the interface.

The following is a sample channel bonding configuration file:

```
Example 4.1. Sample ifcfg-bond0 interface configuration file

DEVICE=bond0
IPADDR=192.168.1.1
NETMASK=255.255.255.0
ONBOOT=yes
BOOTPROTO=None
USERCTL=no
BONDING_OPTS="<bonding parameters separated by spaces>"
```

After the channel bonding interface is created, the network interfaces to be bound together must be configured by adding the `MASTER=` and `SLAVE=` directives to their configuration files. The configuration files for each of the channel-bonded interfaces can be nearly identical.

For example, if two Ethernet interfaces are being channel bonded, both `eth0` and `eth1` may look like the following example:

```
DEVICE=eth<N>
BOOTPROTO=None
ONBOOT=yes
MASTER=bond0
SLAVE=yes
USERCTL=no
```

In this example, replace `<N>` with the numerical value for the interface.

For a channel bonding interface to be valid, the kernel module must be loaded. To ensure that the module is loaded when the channel bonding interface is brought up, create a new file as root named `<bonding>.conf` in the `/etc/modprobe.d/` directory. Note that you can name this file anything you like as long as it ends with a `.conf` extension. Insert the following line in this new file:

```
alias bond<N> bonding
```
Replace <N> with the interface number, such as 0. For each configured channel bonding interface, there must be a corresponding entry in your new /etc/modprobe.d/<bonding>.conf file.

Important: put all bonding module parameters in ifcfg-bondN files

Parameters for the bonding kernel module must be specified as a space-separated list in the BONDING_OPTS="<bonding parameters>" directive in the ifcfg-bond<#> interface file. Do not specify options for the bonding device in /etc/modprobe.d/<bonding>.conf, or in the deprecated /etc/modprobe.conf file. For further instructions and advice on configuring the bonding module and to view the list of bonding parameters, refer to Section 22.7.2, “Using Channel Bonding”.

4.2.3. Alias and Clone Files

Two lesser-used types of interface configuration files are alias and clone files.

Alias interface configuration files, which are used to bind multiple addresses to a single interface, use the ifcfg-<if-name>:<alias-value> naming scheme.

For example, an ifcfg-eth0:0 file could be configured to specify DEVICE=eth0:0 and a static IP address of 10.0.0.2, serving as an alias of an Ethernet interface already configured to receive its IP information via DHCP in ifcfg-eth0. Under this configuration, eth0 is bound to a dynamic IP address, but the same physical network card can receive requests via the fixed, 10.0.0.2 IP address.

Caution

Alias interfaces do not support DHCP.

A clone interface configuration file should use the following naming convention: ifcfg-<if-name>-<clone-name>. While an alias file allows multiple addresses for an existing interface, a clone file is used to specify additional options for an interface. For example, a standard DHCP Ethernet interface called eth0, may look similar to this:

```
DEVICE=eth0
ONBOOT=yes
BOOTPROTO=dhcp

Since the default value for the USERCTL directive is no if it is not specified, users cannot bring this interface up and down. To give users the ability to control the interface, create a clone by copying ifcfg-eth0 to ifcfg-eth0-user and add the following line to ifcfg-eth0-user:

```
USERCTL=yes
```

This way a user can bring up the eth0 interface using the /sbin/ifup eth0-user command because the configuration options from ifcfg-eth0 and ifcfg-eth0-user are combined. While this is a very basic example, this method can be used with a variety of options and interfaces.

The easiest way to create alias and clone interface configuration files is to use the graphical Network Administration Tool. For more information on using this tool, refer to Chapter 5, Network Configuration.
4.2.4. Dialup Interfaces

If you are connecting to the Internet via a dialup connection, a configuration file is necessary for the interface.

PPP interface files are named using the following format:

```
ifcfg-ppp<X>
```

where `<X>` is a unique number corresponding to a specific interface.

The PPP interface configuration file is created automatically when `wvdial`, the Network Administration Tool or `Kppp` is used to create a dialup account. It is also possible to create and edit this file manually.

The following is a typical `ifcfg-ppp0` file:

```
DEVICE=ppp0
NAME=test
WVDIALSECT=test
MODEMPORT=/dev/modem
LINESPEED=115200
PAPNAME=test
USERCTL=true
ONBOOT=no
PERSIST=no
DEFROUTE=yes
PEERDNS=yes
DEMAND=no
IDLETIMEOUT=600
```

Serial Line Internet Protocol (SLIP) is another dialup interface, although it is used less frequently. SLIP files have interface configuration file names such as `ifcfg-sl0`.

Other options that may be used in these files include:

- **DEFRROUTE=<answer>**
  - where `<answer>` is one of the following:
    - **yes** — Set this interface as the default route.
    - **no** — Do not set this interface as the default route.

- **DEMAND=<answer>**
  - where `<answer>` is one of the following:
    - **yes** — This interface allows `pppd` to initiate a connection when someone attempts to use it.
    - **no** — A connection must be manually established for this interface.

- **IDLETIMEOUT=<value>**
  - where `<value>` is the number of seconds of idle activity before the interface disconnects itself.

- **INITSTRING=<string>**
  - where `<string>` is the initialization string passed to the modem device. This option is primarily used in conjunction with SLIP interfaces.

- **LINESPEED=<value>**
  - where `<value>` is the baud rate of the device. Possible standard values include 57600, 38400, 19200, and 9600.
MODEMPORT=<device>
where <device> is the name of the serial device that is used to establish the connection for the interface.

MTU=<value>
where <value> is the Maximum Transfer Unit (MTU) setting for the interface. The MTU refers to the largest number of bytes of data a frame can carry, not counting its header information. In some dialup situations, setting this to a value of 576 results in fewer packets dropped and a slight improvement to the throughput for a connection.

NAME=<name>
where <name> is the reference to the title given to a collection of dialup connection configurations.

PAPNAME=<name>
where <name> is the username given during the Password Authentication Protocol (PAP) exchange that occurs to allow connections to a remote system.

PERSIST=<answer>
where <answer> is one of the following:

• yes — This interface should be kept active at all times, even if deactivated after a modem hang up.

• no — This interface should not be kept active at all times.

REMIP=<address>
where <address> is the IP address of the remote system. This is usually left unspecified.

WVDIALSECT=<name>
where <name> associates this interface with a dialer configuration in /etc/wvdial.conf. This file contains the phone number to be dialed and other important information for the interface.

4.2.5. Other Interfaces
Other common interface configuration files include the following:

ifcfg-lo
A local loopback interface is often used in testing, as well as being used in a variety of applications that require an IP address pointing back to the same system. Any data sent to the loopback device is immediately returned to the host's network layer.

⚠️ Warning
The loopback interface script, /etc/sysconfig/network-scripts/ifcfg-lo, should never be edited manually. Doing so can prevent the system from operating correctly.

ifcfg-irlan0
An infrared interface allows information between devices, such as a laptop and a printer, to flow over an infrared link. This works in a similar way to an Ethernet device except that it commonly occurs over a peer-to-peer connection.
4.3. Interface Control Scripts

The interface control scripts activate and deactivate system interfaces. There are two primary interface control scripts that call on control scripts located in the `/etc/sysconfig/network-scripts/` directory: `/sbin/ifdown` and `/sbin/ifup`.

The `ifup` and `ifdown` interface scripts are symbolic links to scripts in the `/sbin/` directory. When either of these scripts are called, they require the value of the interface to be specified, such as:

```
ifup eth0
```

**Caution**

The `ifup` and `ifdown` interface scripts are the only scripts that the user should use to bring up and take down network interfaces.

The following scripts are described for reference purposes only.

Two files used to perform a variety of network initialization tasks during the process of bringing up a network interface are `/etc/rc.d/init.d/functions` and `/etc/sysconfig/network-scripts/network-functions`. Refer to Section 4.5, "Network Function Files" for more information.

After verifying that an interface has been specified and that the user executing the request is allowed to control the interface, the correct script brings the interface up or down. The following are common interface control scripts found within the `/etc/sysconfig/network-scripts/` directory:

- **ifup-aliases**
  - Configures IP aliases from interface configuration files when more than one IP address is associated with an interface.

- **ifup-ipp** and **ifdown-ipp**
  - Brings ISDN interfaces up and down.

- **ifup-ipv6** and **ifdown-ipv6**
  - Brings IPv6 interfaces up and down.

- **ifup-plip**
  - Brings up a PLIP interface.

- **ifup-plusb**
  - Brings up a USB interface for network connections.

- **ifup-post** and **ifdown-post**
  - Contains commands to be executed after an interface is brought up or down.

- **ifup-ppp** and **ifdown-ppp**
  - Brings a PPP interface up or down.
Chapter 4. Network Interfaces

**ifup-routes**
Adds static routes for a device as its interface is brought up.

**ifdown-sit** and **ifup-sit**
Contains function calls related to bringing up and down an IPv6 tunnel within an IPv4 connection.

**ifup-wireless**
Brings up a wireless interface.

**Warning**
Removing or modifying any scripts in the `/etc/sysconfig/network-scripts/` directory can cause interface connections to act irregularly or fail. Only advanced users should modify scripts related to a network interface.

The easiest way to manipulate all network scripts simultaneously is to use the `/sbin/service` command on the network service (`/etc/rc.d/init.d/network`), as illustrated the following command:

```
/sbin/service network <action>
```

Here, `<action>` can be either `start`, `stop`, or `restart`.

To view a list of configured devices and currently active network interfaces, use the following command:

```
/sbin/service network status
```

### 4.4. Configuring Static Routes
Routing will be configured on routing devices, therefore it should not be necessary to configure static routes on Red Hat Enterprise Linux servers or clients. However, if static routes are required they can be configured for each interface. This can be useful if you have multiple interfaces in different subnets.

Use the `route` command to display the IP routing table.

Static route configuration is stored in a `/etc/sysconfig/network-scripts/route-interface` file. For example, static routes for the eth0 interface would be stored in the `/etc/sysconfig/network-scripts/route-eth0` file. The `route-interface` file has two formats: IP command arguments and network/netmask directives.

#### IP Command Arguments Format
Define a default gateway on the first line. This is only required if the default gateway is not set via DHCP:

```
default X.X.X.X dev interface
```

`X.X.X.X` is the IP address of the default gateway. The `interface` is the interface that is connected to, or can reach, the default gateway.

Define a static route. Each line is parsed as an individual route:
Configuring Static Routes

X.X.X.X/X via X.X.X.X dev interface

X.X.X.X/X is the network number and netmask for the static route. X.X.X.X and interface are the IP address and interface for the default gateway respectively. The X.X.X.X address does not have to be the default gateway IP address. In most cases, X.X.X.X will be an IP address in a different subnet, and interface will be the interface that is connected to, or can reach, that subnet. Add as many static routes as required.

The following is a sample route-eth0 file using the IP command arguments format. The default gateway is 192.168.0.1, interface eth0. The two static routes are for the 10.10.10.0/24 and 172.16.1.0/24 networks:

```
default 192.168.0.1 dev eth0
10.10.10.0/24 via 192.168.0.1 dev eth0
172.16.1.0/24 via 192.168.0.1 dev eth0
```

Static routes should only be configured for other subnets. The above example is not necessary, since packets going to the 10.10.10.0/24 and 172.16.1.0/24 networks will use the default gateway anyway. Below is an example of setting static routes to a different subnet, on a machine in a 192.168.0.0/24 subnet. The example machine has an eth0 interface in the 192.168.0.0/24 subnet, and an eth1 interface (10.10.10.1) in the 10.10.10.0/24 subnet:

```
10.10.10.0/24 via 10.10.10.1 dev eth1
```

**Duplicate Default Gateways**

If the default gateway is already assigned from DHCP, the IP command arguments format can cause one of two errors during start-up, or when bringing up an interface from the down state using the ifup command: "RTNETLINK answers: File exists" or 'Error: either "to" is a duplicate, or "X.X.X.X" is a garbage.', where X.X.X.X is the gateway, or a different IP address. These errors can also occur if you have another route to another network using the default gateway. Both of these errors are safe to ignore.

**Network/Netmask Directives Format**

You can also use the network/netmask directives format for route-interface files. The following is a template for the network/netmask format, with instructions following afterwards:

```
ADDRESS0=X.X.X.X
NETMASK0=X.X.X.X
GATEWAY0=X.X.X.X
```

- **ADDRESS0=X.X.X.X** is the network number for the static route.
- **NETMASK0=X.X.X.X** is the netmask for the network number defined with ADDRESS0=X.X.X.X.
- **GATEWAY0=X.X.X.X** is the default gateway, or an IP address that can be used to reach ADDRESS0=X.X.X.X

The following is a sample route-eth0 file using the network/netmask directives format. The default gateway is 192.168.0.1, interface eth0. The two static routes are for the 10.10.10.0/24 and the 172.16.1.0/24 networks:

```
default 192.168.0.1 dev eth0
10.10.10.0/24 via 192.168.0.1 dev eth0
172.16.1.0/24 via 192.168.0.1 dev eth0
```
Chapter 4. Network Interfaces

172.16.1.0/24 networks. However, as mentioned before, this example is not necessary as the 10.10.10.0/24 and 172.16.1.0/24 networks would use the default gateway anyway:

```
ADDRESS0=10.10.10.0
NETMASK0=255.255.255.0
GATEWAY0=192.168.0.1
ADDRESS1=172.16.1.0
NETMASK1=255.255.255.0
GATEWAY1=192.168.0.1
```

Subsequent static routes must be numbered sequentially, and must not skip any values. For example, ADDRESS0, ADDRESS1, ADDRESS2, and so on.

Below is an example of setting static routes to a different subnet, on a machine in the 192.168.0.0/24 subnet. The example machine has an eth0 interface in the 192.168.0.0/24 subnet, and an eth1 interface (10.10.10.1) in the 10.10.0.0/24 subnet:

```
ADDRESS0=10.10.10.0
NETMASK0=255.255.255.0
GATEWAY0=10.10.10.1
```

DHCP should assign these settings automatically, therefore it should not be necessary to configure static routes on Red Hat Enterprise Linux servers or clients.

4.5. Network Function Files

Red Hat Enterprise Linux makes use of several files that contain important common functions used to bring interfaces up and down. Rather than forcing each interface control file to contain these functions, they are grouped together in a few files that are called upon when necessary.

The `/etc/sysconfig/network-scripts/network-functions` file contains the most commonly used IPv4 functions, which are useful to many interface control scripts. These functions include contacting running programs that have requested information about changes in the status of an interface, setting hostnames, finding a gateway device, verifying whether or not a particular device is down, and adding a default route.

As the functions required for IPv6 interfaces are different from IPv4 interfaces, a `/etc/sysconfig/network-scripts/network-functions-ipv6` file exists specifically to hold this information. The functions in this file configure and delete static IPv6 routes, create and remove tunnels, add and remove IPv6 addresses to an interface, and test for the existence of an IPv6 address on an interface.

4.6. Additional Resources

The following are resources which explain more about network interfaces.

4.6.1. Installed Documentation

```
/usr/share/doc/initscripts-<version>/sysconfig.txt
```

A guide to available options for network configuration files, including IPv6 options not covered in this chapter.

```
/usr/share/doc/iproute-<version>/ip-cref.ps
```

This file contains a wealth of information about the `ip` command, which can be used to manipulate routing tables, among other things. Use the `ggv` or `kghostview` application to view this file.
Network Configuration

*NetworkManager* is a dynamic network control and configuration system that attempts to keep network devices and connections up and active when they are available. *NetworkManager* consists of a core daemon, a GNOME Notification Area applet that provides network status information, and graphical configuration tools that can create, edit and remove connections and interfaces. *NetworkManager* can be used to configure the following types of connections: Ethernet, wireless, mobile broadband (such as cellular 3G), and DSL and PPPoE (Point-to-Point over Ethernet). In addition, *NetworkManager* allows for the configuration of network aliases, static routes, DNS information and VPN connections, as well as many connection-specific parameters. Finally, *NetworkManager* provides a rich API via D-Bus which allows applications to query and control network configuration and state.

Previous versions of Red Hat Enterprise Linux shipped with the Network Administration Tool, which was commonly known as `system-config-network` after its command line invocation. In Red Hat Enterprise Linux 6, *NetworkManager* replaces the former Network Administration Tool while providing enhanced functionality, such as user-specific and mobile broadband configuration. It is also possible to configure the network in Red Hat Enterprise Linux 6 by editing interface configuration files; refer to Chapter 4, Network Interfaces for more information.

*NetworkManager* may be installed by default on Red Hat Enterprise Linux. To ensure that it is, first run the following command as the root user:

```
~# yum install NetworkManager
```

### 5.1. The NetworkManager Daemon

The *NetworkManager* daemon runs with root privileges and is usually configured to start up at boot time. You can determine whether the *NetworkManager* daemon is running by entering this command as root:

```
~# service NetworkManager status
NetworkManager (pid 1527) is running...
```

The `service` command will report *NetworkManager* is stopped if the *NetworkManager* service is not running. To start it for the current session:

```
~# service NetworkManager start
```

Run the `chkconfig` command to ensure that *NetworkManager* starts up every time the system boots:

```
~# chkconfig NetworkManager on
```

For more information on starting, stopping and managing services and runlevels, refer to Chapter 7, Controlling Access to Services.

### 5.2. Interacting with NetworkManager

Users do not interact with the *NetworkManager* system service directly. Instead, you can perform network configuration tasks via *NetworkManager*’s Notification Area applet. The applet has multiple
Chapter 5. Network Configuration

states that serve as visual indicators for the type of connection you are currently using. Hover the pointer over the applet icon for tooltip information on the current connection state.

NetworkManager applet states

If you do not see the NetworkManager applet in the GNOME panel, and assuming that the NetworkManager package is installed on your system, you can start the applet by running the following command as a normal user (not root):

```
$ nm-applet &
```

After running this command, the applet appears in your Notification Area. You can ensure that the applet runs each time you log in by clicking System → Preferences → Startup Applications to open the Startup Applications Preferences window. Then, select the Startup Programs tab and check the box next to NetworkManager.

5.2.1. Connecting to a Network

When you left-click on the applet icon, you are presented with:

- a list of categorized networks you are currently connected to (such as Wired and Wireless);
- a list of all Available Networks NetworkManager has detected;
- options for connecting to any configured Virtual Private Networks (VPNs); and,
- options for connecting to hidden or new wireless networks.

When many networks are available (as when there are many wireless access points in the area), the More networks expandable menu entry appears. If you are connected to a network, its name is presented in bold typeface under its network type, such as Wired or Wireless.
5.2.2. Configuring New and Editing Existing Connections

Next, right-click on the NetworkManager applet to open its context menu, which is the main point of entry for interacting with NetworkManager to configure connections.

Ensure that the Enable Networking box is checked. If the system has detected a wireless card, then you will also see an Enable Wireless menu option. Check the Enable Wireless checkbox as well. NetworkManager notifies you of network connection status changes if you check the Enable Notifications box. Clicking the Connection Information entry presents an informative Connection Information window that lists the connection type and interface, your IP address and routing details, and so on. Useful network information is thus always two clicks away.

Finally, clicking on Edit Connections opens the Network Connections window, from where you can perform most of your network configuration tasks. Note that this window can also be opened by running, as a normal user:
5.2.3. Connecting to a Network Automatically

For any connection type you add or configure, you can choose whether you want NetworkManager to try to connect to that network automatically when it is available.

Procedure 5.1. Configuring NetworkManager to Connect to a Network Automatically When Detected

1. Right-click on the NetworkManager applet icon in the Notification Area and click Edit Connections. The Network Connections window appears.

2. Select the tab for the type of network connection you want to configure.

3. Select the specific connection that you want to configure and click Edit.

4. Check Connect automatically to cause NetworkManager to auto-connect to the connection whenever NetworkManager detects that it is available. Uncheck the checkbox if you do not want NetworkManager to connect automatically. If the box is unchecked, you will have to select that connection manually in the NetworkManager applet’s left-click menu to cause it to connect.

5.2.4. User and System Connections

NetworkManager connections are always either user connections or system connections. Depending on the system-specific policy that the administrator has configured, users may need root privileges to create and modify system connections. NetworkManager’s default policy enables users to create and modify user connections, but requires them to have root privileges to add, modify or delete system connections.

User connections are so-called because they are specific to the user who creates them. In contrast to system connections, whose configurations are stored under the /etc/sysconfig/network-
scripts/ directory (mainly in ifcfg-<network_type> interface configuration files), user connection settings are stored in the GConf configuration database and the GNOME keyring, and are only available during login sessions for the user who created them. Thus, logging out of the desktop session causes user-specific connections to become unavailable.

Tip: Increase security by making VPN connections user-specific

Because NetworkManager uses the GConf and GNOME keyring applications to store user connection settings, and because these settings are specific to your desktop session, it is highly recommended to configure your personal VPN connections as user connections. If you do so, other non-root users on the system cannot view or access these connections in any way.

System connections, on the other hand, become available at boot time and can be used by other users on the system without first logging in to a desktop session.

NetworkManager can quickly and conveniently convert user to system connections and vice versa. Converting a user connection to a system connection causes NetworkManager to create the relevant interface configuration files under the /etc/sysconfig/network-scripts/ directory, and to delete the GConf settings from the user's session. Conversely, converting a system to a user-specific connection causes NetworkManager to remove the system-wide configuration files and create the corresponding GConf/GNOME keyring settings.

Procedure 5.2. Changing a Connection to be User-Specific instead of System-Wide, or Vice-Versa

The Available to all users checkbox controls whether connections are user-specific or system-wide. Depending on the system's policy, root privileges may be required.

1. Right-click on the NetworkManager applet icon in the Notification Area and click Edit Connections. The Network Connections window appears.
2. Select the tab for the type of network connection you want to configure.
3. Select the specific connection that you want to configure and click Edit.
4. Check the Available to all users checkbox to ask NetworkManager to make the connection a system-wide connection. Depending on system policy, you may then be prompted for the root password by the PolicyKit application. If so, enter the root password to finalize the change.

Conversely, uncheck the Available to all users checkbox to make the connection user-specific.
5.3. Configuring Connection Settings

5.3.1. Configuring IPv4 Settings

The IPv4 Settings tab allows you to configure the method by which you connect to the Internet and enter IP address, route, and DNS information as required. The IPv4 Settings tab is available when you create and modify one of the following connection types: wired, wireless, mobile broadband, VPN or DSL.

If you are using DHCP to obtain a dynamic IP address from a DHCP server, you can simply set Method to Automatic (DHCP).
Dynamic Host Configuration Protocol (DHCP)

Dynamic Host Configuration Protocol (DHCP) is a network protocol that automatically assigns TCP/IP information to client machines. Each DHCP client connects to the centrally located DHCP server, which returns that client's network configuration (including the IP address, gateway, and DNS servers).

6.1. Why Use DHCP?

DHCP is useful for automatic configuration of client network interfaces. When configuring the client system, the administrator chooses DHCP instead of specifying an IP address, netmask, gateway, or DNS servers. The client retrieves this information from the DHCP server. DHCP is also useful if an administrator wants to change the IP addresses of a large number of systems. Instead of reconfiguring all the systems, he can just edit one DHCP configuration file on the server for the new set of IP addresses. If the DNS servers for an organization changes, the changes are made on the DHCP server, not on the DHCP clients. When the administrator restarts the network or reboots the clients, the changes will go into effect.

If an organization has a functional DHCP server properly connected to a network, laptops and other mobile computer users can move these devices from office to office.

6.2. Configuring a DHCP Server

The dhcp package contains an ISC DHCP server. First, install the package as the superuser:

```
~]# yum install dhcp
```

Installing the dhcp package creates a file, /etc/dhcp/dhcpd.conf, which is merely an empty configuration file:

```
~]# cat /etc/dhcp/dhcpd.conf
#
# DHCP Server Configuration file.
# see /usr/share/doc/dhcp*/dhcpd.conf.sample
```

The sample configuration file can be found at /usr/share/doc/dhcp-<version>/dhcpd.conf.sample. You should use this file to help you configure /etc/dhcp/dhcpd.conf, which is explained in detail below.

DHCP also uses the file /var/lib/dhcpd/dhcpd.leases to store the client lease database. Refer to Section 6.2.2, "Lease Database" for more information.

6.2.1. Configuration File

The first step in configuring a DHCP server is to create the configuration file that stores the network information for the clients. Use this file to declare options and global options for client systems.

The configuration file can contain extra tabs or blank lines for easier formatting. Keywords are case-insensitive and lines beginning with a hash sign (#) are considered comments.

There are two types of statements in the configuration file:

- Parameters — State how to perform a task, whether to perform a task, or what network configuration options to send to the client.
• Declarations — Describe the topology of the network, describe the clients, provide addresses for the clients, or apply a group of parameters to a group of declarations.

The parameters that start with the keyword option are referred to as options. These options control DHCP options; whereas, parameters configure values that are not optional or control how the DHCP server behaves.

Parameters (including options) declared before a section enclosed in curly brackets ({{}}) are considered global parameters. Global parameters apply to all the sections below it.

**Important**

If the configuration file is changed, the changes do not take effect until the DHCP daemon is restarted with the command `service dhcpd restart`.

**Tip**

Instead of changing a DHCP configuration file and restarting the service each time, using the `omshell` command provides an interactive way to connect to, query, and change the configuration of a DHCP server. By using `omshell`, all changes can be made while the server is running. For more information on `omshell`, refer to the `omshell` man page.

In Example 6.1, “Subnet Declaration”, the `routers`, `subnet-mask`, `domain-search`, `domain-name-servers`, and `time-offset` options are used for any `host` statements declared below it.

Additionally, a `subnet` can be declared, a `subnet` declaration must be included for every subnet in the network. If it is not, the DHCP server fails to start.

In this example, there are global options for every DHCP client in the subnet and a `range` declared. Clients are assigned an IP address within the `range`.

**Example 6.1. Subnet Declaration**

```plaintext
subnet 192.168.1.0 netmask 255.255.255.0 {
    option routers                  192.168.1.254;
    option subnet-mask              255.255.255.0;
    option domain-search              "example.com";
    option domain-name-servers       192.168.1.1;
    option time-offset              -18000;     # Eastern Standard Time
    range 192.168.1.10 192.168.1.100;
}
```

To configure a DHCP server that leases a dynamic IP address to a system within a subnet, modify **Example 6.2, “Range Parameter”** with your values. It declares a default lease time, maximum lease time, and network configuration values for the clients. This example assigns IP addresses in the `range` 192.168.1.10 and 192.168.1.100 to client systems.

**Example 6.2. Range Parameter**

```plaintext
default-lease-time 600;
max-lease-time 7200;
```
option subnet-mask 255.255.255.0;
option broadcast-address 192.168.1.255;
option routers 192.168.1.254;
option domain-name-servers 192.168.1.1, 192.168.1.2;
option domain-search "example.com";
subnet 192.168.1.0 netmask 255.255.255.0 {
    range 192.168.1.10 192.168.1.100;
}

To assign an IP address to a client based on the MAC address of the network interface card, use the `hardware ethernet` parameter within a `host` declaration. As demonstrated in Example 6.3, "Static IP Address using DHCP", the `host apex` declaration specifies that the network interface card with the MAC address 00:A0:78:8E:9E:AA always receives the IP address 192.168.1.4.

Note that the optional parameter `host-name` can also be used to assign a host name to the client.

**Example 6.3. Static IP Address using DHCP**

```
host apex {
    option host-name "apex.example.com";
    hardware ethernet 00:A0:78:8E:9E:AA;
    fixed-address 192.168.1.4;
}
```

All subnets that share the same physical network should be declared within a `shared-network` declaration as shown in Example 6.4, "Shared-network Declaration". Parameters within the `shared-network`, but outside the enclosed `subnet` declarations, are considered to be global parameters. The name of the `shared-network` must be a descriptive title for the network, such as using the title 'test-lab' to describe all the subnets in a test lab environment.

**Example 6.4. Shared-network Declaration**

```
shared-network name {
    option domain-search              "test.redhat.com";
    option domain-name-servers      ns1.redhat.com, ns2.redhat.com;
    option routers                  192.168.0.254;
    more parameters for EXAMPLE shared-network
    subnet 192.168.1.0 netmask 255.255.252.0 {
        parameters for subnet
        range 192.168.1.1 192.168.1.254;
    }
    subnet 192.168.2.0 netmask 255.255.252.0 {
        parameters for subnet
        range 192.168.2.1 192.168.2.254;
    }
}
```

As demonstrated in Example 6.5, "Group Declaration", the `group` declaration is used to apply global parameters to a group of declarations. For example, shared networks, subnets, and hosts can be grouped.

**Example 6.5. Group Declaration**

```
Chapter 6. Dynamic Host Configuration Protocol (DHCP)

```plaintext
group {
  option routers                  192.168.1.254;
  option subnet-mask              255.255.255.0;
  option domain-search              "example.com";
  option domain-name-servers       192.168.1.1;
  option time-offset              -18000;     # Eastern Standard Time

  host apex {
    option host-name "apex.example.com";
    hardware ethernet 00:A0:78:8E:9E:AA;
    fixed-address 192.168.1.4;
  }

  host raleigh {
    option host-name "raleigh.example.com";
    hardware ethernet 00:A1:DD:74:C3:F2;
    fixed-address 192.168.1.6;
  }
}
```

**Tip**

The sample configuration file provided can be used as a starting point and custom configuration options can be added to it. To copy it to the proper location, use the following command:

```
  cp /usr/share/doc/dhcp-<version-number>/dhcpd.conf.sample /etc/dhcp/dhcpd.conf
```

... where `<version-number>` is the DHCP version number.

For a complete list of option statements and what they do, refer to the `dhcp-options` man page.

### 6.2.2. Lease Database

On the DHCP server, the file `/var/lib/dhcpd/dhcpd.leases` stores the DHCP client lease database. Do not change this file. DHCP lease information for each recently assigned IP address is automatically stored in the lease database. The information includes the length of the lease, to whom the IP address has been assigned, the start and end dates for the lease, and the MAC address of the network interface card that was used to retrieve the lease.

All times in the lease database are in Coordinated Universal Time (UTC), not local time.

The lease database is recreated from time to time so that it is not too large. First, all known leases are saved in a temporary lease database. The `dhcpd.leases` file is renamed `dhcpd.leases~` and the temporary lease database is written to `dhcpd.leases`.

The DHCP daemon could be killed or the system could crash after the lease database has been renamed to the backup file but before the new file has been written. If this happens, the `dhcpd.leases` file does not exist, but it is required to start the service. Do not create a new lease file. If you do, all old leases are lost which causes many problems. The correct solution is to rename the `dhcpd.leases~` backup file to `dhcpd.leases` and then start the daemon.
6.2.3. Starting and Stopping the Server

**Important**

When the DHCP server is started for the first time, it fails unless the `dhcpd.leases` file exists. Use the command `touch /var/lib/dhcpd/dhcpd.leases` to create the file if it does not exist.

If the same server is also running BIND as a DNS server, this step is not necessary, as starting the `named` service automatically checks for a `dhcpd.leases` file.

To start the DHCP service, use the command `/sbin/service dhcpd start`. To stop the DHCP server, use the command `/sbin/service dhcpd stop`.

By default, the DHCP service does not start at boot time. To configure the daemon to start automatically at boot time, refer to Chapter 7, Controlling Access to Services.

If more than one network interface is attached to the system, but the DHCP server should only be started on one of the interfaces, configure the DHCP server to start only on that device. In `/etc/sysconfig/dhcpd`, add the name of the interface to the list of `DHCPDARGS`:

```
# Command line options here
DHCPDARGS=eth0
```

This is useful for a firewall machine with two network cards. One network card can be configured as a DHCP client to retrieve an IP address to the Internet. The other network card can be used as a DHCP server for the internal network behind the firewall. Specifying only the network card connected to the internal network makes the system more secure because users can not connect to the daemon via the Internet.

Other command line options that can be specified in `/etc/sysconfig/dhcpd` include:

- `-p <portnum>` — Specifies the UDP port number on which `dhcpd` should listen. The default is port 67. The DHCP server transmits responses to the DHCP clients at a port number one greater than the UDP port specified. For example, if the default port 67 is used, the server listens on port 67 for requests and responses to the client on port 68. If a port is specified here and the DHCP relay agent is used, the same port on which the DHCP relay agent should listen must be specified. Refer to Section 6.2.4, “DHCP Relay Agent” for details.

- `-f` — Runs the daemon as a foreground process. This is mostly used for debugging.

- `-d` — Logs the DHCP server daemon to the standard error descriptor. This is mostly used for debugging. If this is not specified, the log is written to `/var/log/messages`.

- `-cf <filename>` — Specifies the location of the configuration file. The default location is `/etc/dhcp/dhcpd.conf`.

- `-lf <filename>` — Specifies the location of the lease database file. If a lease database file already exists, it is very important that the same file be used every time the DHCP server is started. It is strongly recommended that this option only be used for debugging purposes on non-production machines. The default location is `/var/lib/dhcpd/dhcpd.leases`.

- `-q` — Do not print the entire copyright message when starting the daemon.
6.2.4. DHCP Relay Agent

The DHCP Relay Agent (dhcrelay) allows for the relay of DHCP and BOOTP requests from a subnet with no DHCP server on it to one or more DHCP servers on other subnets.

When a DHCP client requests information, the DHCP Relay Agent forwards the request to the list of DHCP servers specified when the DHCP Relay Agent is started. When a DHCP server returns a reply, the reply is broadcast or unicast on the network that sent the original request.

The DHCP Relay Agent listens for DHCP requests on all interfaces unless the interfaces are specified in /etc/sysconfig/dhcrelay with the INTERFACES directive.

To start the DHCP Relay Agent, use the command `service dhcrelay start`.

6.3. Configuring a DHCP Client

To configure a DHCP client manually, modify the /etc/sysconfig/network file to enable networking and the configuration file for each network device in the /etc/sysconfig/network-scripts directory. In this directory, each device should have a configuration file named ifcfg-eth0, where eth0 is the network device name.

The /etc/sysconfig/network-scripts/ifcfg-eth0 file should contain the following lines:

```
DEVICE=eth0
BOOTPROTO= dhcp
ONBOOT=yes
```

A configuration file is needed for each device to be configured to use DHCP.

Other options for the network script includes:

- **DHCP_HOSTNAME** — Only use this option if the DHCP server requires the client to specify a hostname before receiving an IP address. (The DHCP server daemon in Red Hat Enterprise Linux does not support this feature.)

- **PEERDNS=<answer>**, where <answer> is one of the following:
  - **yes** — Modify /etc/resolv.conf with information from the server. If using DHCP, then yes is the default.
  - **no** — Do not modify /etc/resolv.conf.

If you prefer using a graphical interface, refer to Chapter 5, Network Configuration for instructions on using the Network Administration Tool to configure a network interface to use DHCP.

**Tip**

For advanced configurations of client DHCP options such as protocol timing, lease requirements and requests, dynamic DNS support, aliases, as well as a wide variety of values to override, prepend, or append to client-side configurations, refer to the dhclient and dhclient.conf man pages.
6.4. Configuring a Multihomed DHCP Server

A multihomed DHCP server serves multiple networks, that is, multiple subnets. The examples in these sections detail how to configure a DHCP server to serve multiple networks, select which network interfaces to listen on, and how to define network settings for systems that move networks.

Before making any changes, back up the existing `/etc/sysconfig/dhcpd` and `/etc/dhcp/dhcpd.conf` files.

The DHCP daemon listens on all network interfaces unless otherwise specified. Use the `/etc/sysconfig/dhcpd` file to specify which network interfaces the DHCP daemon listens on. The following `/etc/sysconfig/dhcpd` example specifies that the DHCP daemon listens on the `eth0` and `eth1` interfaces:

```
DHCPDARGS="eth0 eth1;"
```

If a system has three network interfaces cards -- `eth0`, `eth1`, and `eth2` -- and it is only desired that the DHCP daemon listens on `eth0`, then only specify `eth0` in `/etc/sysconfig/dhcpd`:

```
DHCPDARGS="eth0;"
```

The following is a basic `/etc/dhcp/dhcpd.conf` file, for a server that has two network interfaces, `eth0` in a 10.0.0.0/24 network, and `eth1` in a 172.16.0.0/24 network. Multiple subnet declarations allow different settings to be defined for multiple networks:

```
default-lease-time 600;
max-lease-time 7200;
subnet 10.0.0.0 netmask 255.255.255.0 {
  option subnet-mask 255.255.255.0;
  option routers 10.0.0.1;
  range 10.0.0.5 10.0.0.15;
}
subnet 172.16.0.0 netmask 255.255.255.0 {
  option subnet-mask 255.255.255.0;
  option routers 172.16.0.1;
  range 172.16.0.5 172.16.0.15;
}
```

A subnet declaration is required for every network your DHCP server is serving. Multiple subnets require multiple subnet declarations. If the DHCP server does not have a network interface in a range of a subnet declaration, the DHCP server does not serve that network.

If there is only one subnet declaration, and no network interfaces are in the range of that subnet, the DHCP daemon fails to start, and an error such as the following is logged to `/var/log/messages`:

```
dhcpd: No subnet declaration for eth0 (0.0.0.0).
dhcpd: ** Ignoring requests on eth0. If this is not what you want, please write a subnet declaration dhcpd: in your dhcpd.conf file for the network segment dhcpd: to which interface eth1 is attached. **
```
options subnet-mask 255.255.255.0;
    The option subnet-mask option defines a subnet mask, and overrides the netmask value in the subnet declaration. In simple cases, the subnet and netmask values are the same.

option routers 10.0.0.1;
    The option routers option defines the default gateway for the subnet. This is required for systems to reach internal networks on a different subnet, as well as external networks.

range 10.0.0.5 10.0.0.15;
    The range option specifies the pool of available IP addresses. Systems are assigned an address from the range of specified IP addresses.

For further information, refer to the dhcpd.conf(5) man page.

### Aliases Interfaces

Alias interfaces are not supported by DHCP. If an alias interface is the only interface, in the only subnet specified in /etc/dhcp/dhcpd.conf, the DHCP daemon fails to start.

### 6.4.1. Host Configuration

Before making any changes, back up the existing /etc/sysconfig/dhcpd and /etc/dhcp/dhcpd.conf files.

**Configuring a single system for multiple networks**

The following /etc/dhcp/dhcpd.conf example creates two subnets, and configures an IP address for the same system, depending on which network it connects to:

```plaintext

default-lease-time 600;
max-lease-time 7200;
subnet 10.0.0.0 netmask 255.255.255.0 {
    option subnet-mask 255.255.255.0;
    option routers 10.0.0.1;
    range 10.0.0.5 10.0.0.15;
}
subnet 172.16.0.0 netmask 255.255.255.0 {
    option subnet-mask 255.255.255.0;
    option routers 172.16.0.1;
    range 172.16.0.5 172.16.0.15;
}
host example0 {
    hardware ethernet 00:1A:6B:6A:2E:0B;
    fixed-address 10.0.0.20;
}
host example1 {
    hardware ethernet 00:1A:6B:6A:2E:0B;
    fixed-address 172.16.0.20;
}
```

**host example0**

The host declaration defines specific parameters for a single system, such as an IP address. To configure specific parameters for multiple hosts, use multiple host declarations.
Most DHCP clients ignore the name in `host` declarations, and as such, this name can anything, as long as it is unique to other `host` declarations. To configure the same system for multiple networks, use a different name for each `host` declaration, otherwise the DHCP daemon fails to start. Systems are identified by the `hardware ethernet` option, not the name in the `host` declaration.

```
software ethernet 00:1A:6B:6A:2E:0B;
```

The `hardware ethernet` option identifies the system. To find this address, run the `ip link` command.

```
fixed-address 10.0.0.20;
```

The `fixed-address` option assigns a valid IP address to the system specified by the `hardware ethernet` option. This address must be outside the IP address pool specified with the `range` option.

If `option` statements do not end with a semicolon, the DHCP daemon fails to start, and an error such as the following is logged to `/var/log/messages`:

```
/etc/dhcp/dhcpd.conf line 20: semicolon expected.
dhcpd: }  
dhcpd: ^  
dhcpd: /etc/dhcp/dhcpd.conf line 38: unexpected end of file  
dhcpd: }  
dhcpd: ^  
dhcpd: Configuration file errors encountered -- exiting
```

**Configuring systems with multiple network interfaces**

The following `host` declarations configure a single system, that has multiple network interfaces, so that each interface receives the same IP address. This configuration will not work if both network interfaces are connected to the same network at the same time:

```
host interface0 {
  hardware ethernet 00:1a:6b:6a:2e:0b;
  fixed-address 10.0.0.18;
}
host interface1 {
  hardware ethernet 00:1A:6B:6A:27:3A;
  fixed-address 10.0.0.18;
}
```

For this example, `interface0` is the first network interface, and `interface1` is the second interface. The different `hardware ethernet` options identify each interface.

If such a system connects to another network, add more `host` declarations, remembering to:

- assign a valid `fixed-address` for the network the host is connecting to.
- make the name in the `host` declaration unique.

When a name given in a `host` declaration is not unique, the DHCP daemon fails to start, and an error such as the following is logged to `/var/log/messages`:

```
dhcpd: /etc/dhcp/dhcpd.conf line 31: host interface0: already exists
```

```
dhcpd: }
```
Chapter 6. Dynamic Host Configuration Protocol (DHCP)

This error was caused by having multiple **host interface0** declarations defined in `/etc/dhcp/dhcpd.conf`.

### 6.5. DHCP for IPv6 (DHCPv6)

The ISC DHCP includes support for IPv6 (DHCPv6) since the 4.x release with a DHCPv6 server, client and relay agent functionality. The server, client and relay agents support both IPv4 and IPv6. However, the client and the server can only manage one protocol at a time — for dual support they must be started separately for IPv4 and IPv6.

The DHCPv6 server configuration file can be found at `/etc/dhcp/dhcpd6.conf`.

The sample server configuration file can be found at `/usr/share/doc/dhcp-<version>/dhcpd6.conf.sample`.

To start the DHCPv6 service, use the command `/sbin/service dhcpd6 start`.

A simple DHCPv6 server configuration file can look like this:

```plaintext
subnet6 2001:db8:0:1::/64 {
    range6 2001:db8:0:1::129 2001:db8:0:1::254;
    option dhcp6.name-servers fec0:0:0:1::1;
    option dhcp6.domain-search "domain.example";
}
```

### 6.6. Additional Resources

For additional information, refer to *The DHCP Handbook; Ralph Droms and Ted Lemon; 2003* or the following resources.

#### 6.6.1. Installed Documentation

- **dhcpd** man page — Describes how the DHCP daemon works.

- **dhcpd.conf** man page — Explains how to configure the DHCP configuration file; includes some examples.

- **dhcpd.leases** man page — Describes a persistent database of leases.

- **dhcp-options** man page — Explains the syntax for declaring DHCP options in `dhcpd.conf`; includes some examples.

- **dhcrelay** man page — Explains the DHCP Relay Agent and its configuration options.

Controlling Access to Services

Maintaining security on your system is extremely important, and one approach for this task is to manage access to system services carefully. Your system may need to provide open access to particular services (for example, httpd if you are running a web server). However, if you do not need to provide a service, you should turn it off to minimize your exposure to possible bug exploits.

This chapter explains the concept of runlevels, and describes how to set the default one. It also covers the setup of the services to be run in each of them using three different utilities: the Service Configuration graphical application, the ntsysv text user interface, and the chkconfig command line tool. Finally, it describes how to start, stop, and restart the services on a command line using the service command.

Important

When you allow access for new services, always remember that both the firewall and SELinux need to be configured as well. One of the most common mistakes committed when configuring a new service is neglecting to implement the necessary firewall configuration and SELinux policies to allow access for it. Refer to the Red Hat Enterprise Linux Security Guide (see Section 7.4, “Additional Resources”) for more information.

7.1. Configuring the Default Runlevel

A runlevel is a state, or mode, defined by services that are meant to be run when this runlevel is selected. Seven numbered runlevels exist (indexed from 0):

<table>
<thead>
<tr>
<th>Runlevel</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Used to halt the system. This runlevel is reserved and cannot be changed.</td>
</tr>
<tr>
<td>1</td>
<td>Used to run in a single-user mode. This runlevel is reserved and cannot be changed.</td>
</tr>
<tr>
<td>2</td>
<td>Not used by default. You are free to define it yourself.</td>
</tr>
<tr>
<td>3</td>
<td>Used to run in a full multi-user mode with a command line user interface.</td>
</tr>
<tr>
<td>4</td>
<td>Not used by default. You are free to define it yourself.</td>
</tr>
<tr>
<td>5</td>
<td>Used to run in a full multi-user mode with a graphical user interface.</td>
</tr>
<tr>
<td>6</td>
<td>Used to reboot the system. This runlevel is reserved and cannot be changed.</td>
</tr>
</tbody>
</table>

To check in which runlevel you are operating, type the following:

```
~$ runlevel
N 5
```

The runlevel command displays previous and current runlevel. In this case it is number 5, which means the system is running in a full multi-user mode with a graphical user interface.

The default runlevel can be changed by modifying the /etc/inittab file, which contains a line near the end of the file similar to the following:

```
id:5:initdefault:
```
In order to edit this file, you must have superuser privileges. To obtain them, log in as root by typing the following command:

```
~$ su -
Password:
```

Now open the file in a text editor such as `vi` or `nano`:

```
~# nano /etc/inittab
```

Then change the number in this line to the desired value and exit the editor. Note that the change does not take effect until you reboot the system.

### 7.2. Configuring the Services

#### 7.2.1. Using the Service Configuration Utility

The **Service Configuration** utility is a graphical application developed by Red Hat to configure which services are started at boot time, as well as to start, stop, and restart them from the menu.

To start the utility, select **System → Administration → Services** from the panel, or type the command `system-config-services` at a shell prompt (e.g., `xterm` or `GNOME Terminal`).

The utility displays the list of all available services (i.e., both the services from the `/etc/rc.d/` directory, and the services controlled by `xinetd`) along with their description and the current status. See Table 7.2, “Possible Service States” for a complete list of used icons and an explanation of their meaning.

![The Service Configuration Utility](image)

**Figure 7.1. The Service Configuration Utility**

The utility displays the list of all available services (i.e., both the services from the `/etc/rc.d/` directory, and the services controlled by `xinetd`) along with their description and the current status. See Table 7.2, “Possible Service States” for a complete list of used icons and an explanation of their meaning.

Table 7.2. Possible Service States

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![green_circle]</td>
<td>The service is enabled.</td>
</tr>
<tr>
<td>![red_circle]</td>
<td>The service is disabled.</td>
</tr>
</tbody>
</table>
Using the **Service Configuration** Utility

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Icon]</td>
<td>The service is enabled for selected runlevels only.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>The service is running.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>The service is stopped.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>There is something wrong with the service.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>The status of the service is unknown.</td>
</tr>
</tbody>
</table>

Unless you are already authenticated, you will be prompted to enter the superuser password the first time you make a change:

![Managing system services requires authentication](image)

An application is attempting to perform an action that requires privileges. Authentication as the super user is required to perform this action.

Password for root: 

![Details](image)

Figure 7.2. Authentication Query

### 7.2.1.1. Enabling the Service
To enable a service, select it from the list and either click the **Enable** button on the toolbar, or choose **Service → Enable** from the main menu.

### 7.2.1.2. Disabling the Service
To disable the service, select it from the list and either click the **Disable** button on the toolbar, or choose **Service → Disable** from the main menu.

### 7.2.1.3. Running the Service
To run the service, select it from the list and either click the **Start** button on the toolbar, or choose **Service → Start** from the main menu. Note that this option is not available for services controlled by `xinetd`, as they are started by it on demand.

### 7.2.1.4. Stopping the Service
To stop the service, select it from the list and either click the **Stop** button on the toolbar, or choose **Service → Stop** from the main menu. Note that this option is not available for services controlled by `xinetd`, as they are stopped by it when their job is finished.
Chapter 7. Controlling Access to Services

7.2.1.5. Restarting the Running Service
To restart the running service, select it from the list and either click the **Restart** button on the toolbar, or choose **Service → Restart** from the main menu. Note that this option is not available for services controlled by **xinetd**, as they are started and stopped by it automatically.

7.2.1.6. Selecting the Runlevels
To enable the service for certain runlevels only, select it from the list and either click the **Customize** button on the toolbar, or choose **Service → Customize** from the main menu. Then select the checkbox beside each runlevel in which you want the service to run. Note that this option is not available for services controlled by **xinetd**.

7.2.2. Using the **ntsysv** Utility
The **ntsysv** utility is a command line application with a simple text user interface to configure which services are to be started in selected runlevels. Note that in order to use the utility, you must obtain superuser privileges first:

```
~]$ su -
Password:
```

To start the utility, type the following command:

```
~]# ntsysv
```

The utility displays the list of available services (i.e., the services from the `/etc/rc.d/init.d/` directory) along with their current status and a description obtainable by pressing **F1**. See **Table 7.3, “Possible Service States”** for a list of used symbols and an explanation of their meaning.

### Table 7.3. Possible Service States

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[*]</td>
<td>The service is enabled.</td>
</tr>
</tbody>
</table>
7.2.1. Enabling the Service
To enable a service, navigate through the list using the **Up** and **Down** arrows keys, and select it with the **Spacebar**. An asterisk (*) should appear in the brackets. Once you are done, use **Tab** to navigate to the **Ok** button, and confirm the changes by pressing **Enter**.

Please, keep in mind that **ntsysv** does not actually run the service. If you need to start the service immediately, use the **service** command as described in Section 7.3.1.1, “Running the Service”.

7.2.2. Disabling the Service
To disable a service, navigate through the list using the **Up** and **Down** arrows keys, and toggle its status with the **Spacebar**. An asterisk (*) in the brackets should disappear. Once you are done, use **Tab** to navigate to the **Ok** button, and confirm the changes by pressing **Enter**.

Please, keep in mind that **ntsysv** does not actually stop the service. If you need to stop the service immediately, use the **service** command as described in Section 7.3.1.2, “Stopping the Service”.

7.2.3. Selecting the Runlevels
By default, the **ntsysv** utility affects the current runlevel only. To enable or disable services for other runlevels, run the command with the additional **--level** option followed by the string of numbers from 0 to 6 representing each runlevel you want to configure. For example, to configure runlevels 3 and 5, type:

```
~# ntsysv --level 35
```

7.2.3. Using the **chkconfig** Utility
The **chkconfig** utility is a command line application to configure which services are to be started in selected runlevels. It also allows you to list all available services along with their current setting. Note that with the exception of listing, you must have superuser privileges to use this command. To obtain them, log in as root by typing:

```
~$ su -
Password:
```

7.2.3.1. Listing the Services
To display a list of system services (i.e., both the services from the **/etc/rc.d/init.d/** directory, and the services controlled by **xinetd**), either type **chkconfig --list**, or use **chkconfig** with no additional arguments. You should be presented with an output similar to this:

```
Example 7.1. Listing the services

<table>
<thead>
<tr>
<th>Service</th>
<th>0:off</th>
<th>1:off</th>
<th>2:off</th>
<th>3:on</th>
<th>4:off</th>
<th>5:off</th>
<th>6:off</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetworkManager</td>
<td>0:off</td>
<td>1:off</td>
<td>2:off</td>
<td>3:on</td>
<td>4:off</td>
<td>5:off</td>
<td>6:off</td>
</tr>
<tr>
<td>abrtd</td>
<td>0:off</td>
<td>1:off</td>
<td>2:off</td>
<td>3:off</td>
<td>4:off</td>
<td>5:off</td>
<td>6:off</td>
</tr>
<tr>
<td>acpid</td>
<td>0:off</td>
<td>1:off</td>
<td>2:off</td>
<td>3:off</td>
<td>4:off</td>
<td>5:off</td>
<td>6:off</td>
</tr>
<tr>
<td>anamon</td>
<td>0:off</td>
<td>1:off</td>
<td>2:off</td>
<td>3:off</td>
<td>4:off</td>
<td>5:off</td>
<td>6:off</td>
</tr>
</tbody>
</table>
```

81
Chapter 7. Controlling Access to Services

<table>
<thead>
<tr>
<th>Service</th>
<th>Runlevel 0</th>
<th>Runlevel 1</th>
<th>Runlevel 2</th>
<th>Runlevel 3</th>
<th>Runlevel 4</th>
<th>Runlevel 5</th>
<th>Runlevel 6</th>
</tr>
</thead>
<tbody>
<tr>
<td>atd</td>
<td>off</td>
<td>on</td>
<td>off</td>
<td>on</td>
<td>on</td>
<td>on</td>
<td>off</td>
</tr>
<tr>
<td>auditd</td>
<td>off</td>
<td>on</td>
<td>off</td>
<td>on</td>
<td>on</td>
<td>on</td>
<td>off</td>
</tr>
<tr>
<td>avahi-daemon</td>
<td>off</td>
<td>on</td>
<td>off</td>
<td>on</td>
<td>on</td>
<td>on</td>
<td>off</td>
</tr>
<tr>
<td>... several lines omitted ...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>wpa_supplicant</td>
<td>off</td>
<td>off</td>
<td>off</td>
<td>off</td>
<td>off</td>
<td>off</td>
<td>off</td>
</tr>
</tbody>
</table>

xinetd based services:
- chargen-dgram: off
- chargen-stream: off
- cvs: off
- daytime-dgram: off
- daytime-stream: off
- discard-dgram: off
- ... several lines omitted ...
- time-stream: off

As you can see, each line consists of the name of the service followed by its status (on or off) for each of the seven numbered runlevels. For example, in the listing above, NetworkManager is enabled for runlevel 2, 3, 4, and 5, while abrtd runs in runlevel 3 and 5. The xinetd based services are listed at the end, being either on, or off.

To display the current settings for selected service only, use `chkconfig --list` followed by the name of the service:

Example 7.2. Listing a single service

```bash
~]# chkconfig --list sshd
sshd            0:off   1:off   2:on    3:on    4:on    5:on    6:off
```

You can also use `chkconfig --list <service>` to display the status of a service that is managed by xinetd. In that case, the output will simply contain the information whether the service is enabled or disabled:

Example 7.3. Listing a service that is managed by xinetd

```bash
~]# chkconfig --list rsync
rsync           off
```

7.2.3.2. Enabling the Service

To enable the service for runlevels 2, 3, 4, and 5 at the same time, type `chkconfig <service> on`. For instance:

```bash
~]# chkconfig httpd on
```

To enable the service for certain runlevels only, add the `-level` option followed by the string of numbers from 0 to 6 representing each runlevel in which you want the service to run. For example, to enable the abrtd for runlevels 3 and 5, type:

```bash
~]# chkconfig abrtd on --level 35
```

The service will be started the next time you enter one of these runlevels. If you need to start the service immediately, use the `service` command as described in Section 7.3.1.1, “Running the Service”. 

82
To enable the service that is managed by `xinetd`, use `chkconfig <service> on` only, as the `--level` option is not allowed:

```
-]# chkconfig rsync on
```

If the `xinetd` daemon is running, the service is immediately enabled without having to restart the daemon manually.

### 7.2.3.3. Disabling the Service

To disable the service for runlevels 2, 3, 4, and 5 at the same time, type `chkconfig <service> off`. For instance:

```
-]# chkconfig httpd off
```

To disable the service for certain runlevels only, add the `--level` option followed by the string of numbers from 0 to 6 representing each runlevel in which you do not want the service to run. For example, to disable the `abrdt` for runlevels 2 and 4, type:

```
-]# chkconfig abrdt off --level 24
```

The service will be stopped the next time you enter one of these runlevels. If you need to stop the service immediately, use the `service` command as described in Section 7.3.1.2, "Stopping the Service".

To disable the service that is managed by `xinetd`, use `chkconfig <service> off` only, as the `--level` option is not allowed:

```
-]# chkconfig rsync off
```

If the `xinetd` daemon is running, the service is immediately disabled without having to restart the daemon manually.

### 7.3. Running the Services

#### 7.3.1. Using the `service` Utility

The `service` utility enables you to start, stop, or restart the services from the `/etc/init.d/` directory. To use it, make sure you have superuser privileges:

```
-]$ su -
Password:
```

**Tip**

If you are running a graphical user interface, you can also use the Service Configuration utility. See Section 7.2.1, “Using the Service Configuration Utility” for more information.

#### 7.3.1.1. Running the Service

To run the service, type `service <service_name> start`. For example:
Chapter 7. Controlling Access to Services

~]# service httpd start
Starting httpd: [ OK ]

7.3.1.2. Stopping the Service
To stop the service, type `service <service_name> stop`. For example:

~]# service httpd stop
Stopping httpd: [ OK ]

7.3.1.3. Restarting the Service
To restart the service, type `service <service_name> restart`. For example:

~]# service httpd restart
Stopping httpd: [ OK ]
Starting httpd: [ OK ]

7.3.1.4. Checking the Service Status
To check the current status of the service, type `service <service_name> status`. For example:

Example 7.4. Checking the status of `httpd`

~]# service httpd status
httpd (pid  7474) is running...

You can also display the status of all available services at once using the `--status-all` option:

Example 7.5. Checking the status of all services

~]# service --status-all
abrt (pid  1492) is running...
acpid (pid  1305) is running...
atd (pid  1540) is running...
auditd (pid  1103) is running...
atomount (pid 1315) is running...
Avahi daemon is running
cpuspeed is stopped
... several lines omitted ...
wpa_supplicant (pid  1227) is running...

7.4. Additional Resources

7.4.1. Installed Documentation

`man chkconfig`
The manual page for the `chkconfig` utility containing the full documentation on its usage.

`man ntsysv`
The manual page for the `ntsysv` utility containing the full documentation on its usage.
man service
   The manual page for the service utility containing the full documentation on its usage.

man system-config-services
   The manual page for the system-config-services utility containing the full documentation on its usage.

7.4.2. Related Books

Security Guide
   A guide to securing Red Hat Enterprise Linux. It contains valuable information on how to set up the firewall, as well as the configuration of SELinux.
Chapter 8.

Authentication Configuration

8.1. The Authentication Configuration Tool

When a user logs in to a Red Hat Enterprise Linux system, the username and password combination must be verified, or authenticated, as a valid and active user. Sometimes the information to verify the user is located on the local system, and other times the system defers the authentication to a user database on a remote system.

The Authentication Configuration Tool provides a graphical interface for configuring user information retrieval from Lightweight Directory Access Protocol (LDAP), Network Information Service (NIS), and Winbind user account databases. This tool also allows you to configure Kerberos to be used as the authentication protocol when using LDAP or NIS.

**Note**

If you configured a medium or high security level during installation (or with the Security Level Configuration Tool), then the firewall will prevent NIS authentication. For more information about firewalls, refer to the “Firewalls“ section of the Red Hat Enterprise Linux 6 Security Guide.

To start the graphical version of the Authentication Configuration Tool from the desktop, click System → Administration → Authentication or type the command `system-config-authentication` at a shell prompt (for example, in an XTerm or a GNOME terminal).

**Important**

After exiting the authentication program, any changes you made take effect immediately.

8.1.1. Identity & Authentication

The Identity & Authentication tab allows you to configure how users should be authenticated, and has several options for each method of authentication. To select which user account database should be used, select an option from the drop-down list.
Chapter 8. Authentication Configuration

Figure 8.1. Identity & Authentication; changing the option in the User Account Database drop-down list changes the contents of the tab.

The following list explains what each option configures:

**LDAP**

The **LDAP** option instructs the system to retrieve user information via LDAP. It contains the following specifications:

- **LDAP Search Base DN** — Specifies that user information should be retrieved using the listed Distinguished Name (DN).
- **LDAP Server** — Specifies the address of the LDAP server.
- **Use TLS to encrypt connections** — When enabled, Transport Layer Security (TLC) will be used to encrypt passwords sent to the LDAP server. The **Download CA Certificate** option allows
you to specify a URL from which to download a valid Certificate Authority certificate (CA). A valid CA certificate must be in the Privacy Enhanced Mail (PEM) format.

**Important**

The Use TLS to encrypt connections option must not be ticked if an ldaps:// server address is specified in the LDAP Server field.

For more information about CA Certificates, refer to Section 11.6.1, “An Overview of Certificates and Security”.

The openldap-clients package must be installed for this option to work.

LDAP provides the following methods of authentication:

- **Kerberos password** — This option enables Kerberos authentication. It contains the following specifications:
  - **Realm** — Configures the realm for the Kerberos server. The realm is the network that uses Kerberos, composed of one or more KDCs and a potentially large number of clients.
  - **KDCs** — Defines the Key Distribution Centers (KDC), which are servers that issue Kerberos tickets.
  - **Admin Servers** — Specifies the administration server(s) running kadmind.

The Kerberos Settings dialog also allows you to use DNS to resolve hosts to realms and locate KDCs for realms.

The krb5-libs and krb5-workstation packages must be installed for this option to work. For more information about Kerberos, refer to section Using Kerberos of the Red Hat Enterprise Linux 6 Managing Single Sign-On and Smart Cards guide.

- **LDAP password** — This option instructs standard PAM-enabled applications to use LDAP authentication with options specified in the User Account Configuration of LDAP. When using this option, you must provide an ldaps:// server address or use TLS for LDAP authentication.

**Note**

The SSSD service is used as a client for LDAP and Kerberos servers. Thus, offline login is enabled and supported by default. No user interaction is needed to set up the SSSD service with the Authentication Configuration Tool. For more information about the SSSD service, refer to Section 8.2, “The System Security Services Daemon (SSSD)”

**NIS**

The NIS option configures the system to connect to a NIS server (as an NIS client) for user and password authentication. To configure this option, specify the NIS domain and NIS server. If the NIS server is not specified, the daemon attempts to find it via broadcast.

The ypbind package must be installed for this option to work. If the NIS user account database is used, the portmap and ypbind services are started and are also enabled to start at boot time.

For more information about NIS, refer to section “Securing NIS” of the Red Hat Enterprise Linux 6 Security Guide.
Chapter 8. Authentication Configuration

NIS provides the following methods of authentication:

- **Kerberos password** — This option enables Kerberos authentication. For more information about configuration of the Kerberos authentication method, refer to the previous section on LDAP.

- **NIS password** — This option enables NIS authentication. NIS can provide authentication information to outside processes to authenticate users.

**Winbind**

The **Winbind** option configures the system to connect to a Windows Active Directory or a Windows domain controller. User information from the specified directory or domain controller can then be accessed, and server authentication options can be configured. It contains the following specifications:

- **Winbind Domain** — Specifies the Windows Active Directory or domain controller to connect to.

- **Security Model** — Allows you to select a security model, which configures the Samba client mode of operation. The drop-down list allows you to select any of the following:
  - **ads** — This mode instructs Samba to act as a domain member in an Active Directory Server (ADS) realm. To operate in this mode, the `krb5-server` package must be installed, and Kerberos must be configured properly.
  - **domain** — In this mode, Samba will attempt to validate the username/password by authenticating it through a Windows NT Primary or Backup Domain Controller, similar to how a Windows NT Server would.
  - **server** — In this mode, Samba will attempt to validate the username/password by authenticating it through another SMB server (for example, a Windows NT Server). If the attempt fails, the **user** mode will take effect instead.
  - **user** — This is the default mode. With this level of security, a client must first log in with a valid username and password. Encrypted passwords can also be used in this security mode.

- **Winbind ADS Realm** — When the **ads** Security Model is selected, this allows you to specify the ADS Realm the Samba server should act as a domain member of.

- **Winbind Domain Controllers** — Use this option to specify which domain controller **winbind** should use.

- **Template Shell** — When filling out the user information for a Windows NT user, the **winbindd** daemon uses the value chosen here to to specify the login shell for that user.

- **Allow offline login** — By checking this option, you allow authentication information to be stored in a local cache (provided by SSSD). This information is then used when a user attempts to authenticate while offline.

Winbind provides only one method of authentication, **Winbind password**. This method of authentication uses the options specified in the User Account Configuration of Winbind to connect to a Windows Active Directory or a Windows domain controller.

**8.1.2. Advanced Options**

This tab allows you to configure advanced options, as listed below.
**Local Authentication Options**

- **Enable fingerprint reader support** — By checking this option, you enable fingerprint authentication to log in by scanning your finger with the fingerprint reader.

- **Enable local access control** — When enabled, `/etc/security/access.conf` is consulted for authorization of a user.
• **Password Hashing Algorithm** — This option lets you specify which hashing or cryptographic algorithm should be used to encrypt locally stored passwords.

### Other Authentication Options

**Create home directories on the first login** — When enabled, the user's home directory is automatically created when they log in if it does not already exist.

### Smart Card Authentication Options

**Enable smart card support** — This option enables smart card authentication. Smart card authentication allows you to log in using a certificate and a key associated with a smart card.

When the **Enable smart card support** option is checked, the following options can be specified:

- **Card Removal Action** — This option defines what action the system performs when the card is removed from the card reader during an active session. Two alternatives are available:
  - **Ignore** — The card removal is ignored and the system continues to function as normal.
  - **Lock** — The current session is immediately locked.

- **Require smart card login** — Requires the user to login and authenticate with a smart card. It essentially disables any other type of password authentication. This option should not be selected until after you have successfully logged in using a smart card.

The *pam_pkcs11* and the *coolkey* packages must be installed for this option to work. For more information about smart cards, refer to the Red Hat Enterprise Linux 6 *Managing Single Sign-On and Smart Cards* guide.

#### Note

You can restore all of the options specified in the **Authentication Configuration Tool** to the previous configuration setup by clicking **Revert**.

### 8.1.3. Command Line Version

The **Authentication Configuration Tool** also supports a command line interface. The command line version can be used in a configuration script or a kickstart script. The authentication options are summarized in **Table 8.1, “Command Line Options”**.

#### Tip

These options can also be found in the *authconfig* man page or by typing `authconfig --help` at the shell prompt.

<table>
<thead>

The System Security Services Daemon (SSSD)

8.2. The System Security Services Daemon (SSSD)

This section provides an introduction to the System Security Services Daemon (SSSD), the main features that it provides, and discusses the requirements and any limitations of a typical SSSD deployment.

This section also describes how to configure SSSD, and how to use the features that it provides. It provides information on the types of services that it supports and how to configure them, and introduces and describes the most important configuration options. Sample configuration files are also provided to help you optimize your deployment.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--disablepamaccess</td>
<td>Do not check /etc/security/access.conf during account authorization</td>
</tr>
<tr>
<td>--enablemkhomedir</td>
<td>Create a home directory for a user on the first login</td>
</tr>
<tr>
<td>--disablemkhomedir</td>
<td>Do not create a home directory for a user on the first login</td>
</tr>
<tr>
<td>--enablesmartcard</td>
<td>Enable authentication with a smart card</td>
</tr>
<tr>
<td>--disablesmartcard</td>
<td>Disable authentication with a smart card</td>
</tr>
<tr>
<td>--enblerequiresmartcard</td>
<td>Require smart card for authentication</td>
</tr>
<tr>
<td>--disablerequiresmartcard</td>
<td>Do not require smart card for authentication</td>
</tr>
<tr>
<td>--smartcardmodule=&lt;module&gt;</td>
<td>Default smart card module to use</td>
</tr>
<tr>
<td>--smartcardaction=&lt;0=Lock</td>
<td>1=Ignore&gt;</td>
</tr>
<tr>

<td>Restore a backup of all configuration files</td>
</tr>
<tr>
<td>--restorelastbackup</td>
<td>Restore the backup of configuration files saved before the previous configuration change</td>
</tr>
</tbody>
</table>
8.2.1. What is SSSD?
The System Security Services Daemon (SSSD) is a service which provides access to different identity and authentication providers. You can configure SSSD to use a native LDAP domain (that is, an LDAP identity provider with LDAP authentication), or an LDAP identity provider with Kerberos authentication. It provides an NSS and PAM interface to the system, and a pluggable back-end system to connect to multiple different account sources.

SSSD is also extensible; you can configure it to use new identity sources and authentication mechanisms should they arise. In addition, SSSD is fully IPv6-compatible, provided that it is built against c-ares 1.7.1 or later and krb5-libs 1.8.1 or later.

8.2.2. SSSD Features

8.2.2.1. Offline Authentication
One of the primary benefits of SSSD is offline authentication. This solves the case of users having a separate corporate account and a local machine account because of the common requirement to implement a Virtual Private Network (VPN).

SSSD can cache remote identities and authentication credentials. This means that you can still authenticate with these remote identities even when a machine is offline. In an SSSD system, you only need to manage one account.

8.2.2.2. Server Load Reduction
The use of SSSD also helps to reduce the load on identification servers. For example, using nss_ldap, every client application that needs to request user information opens its own connection to the LDAP server. Managing these multiple connections can lead to a heavy load on the LDAP server. In an SSSD system, only the SSSD Data Provider process actually communicates with the LDAP server, reducing the load to one connection per client system.

8.2.2.3. Support for Multiple Domains
You can use SSSD to specify multiple domains of the same type. Compare this to an nsswitch.conf file configuration, with which you can only request user information from a single server of any particular type (LDAP, NIS, etc.). With SSSD, you can create multiple domains of the same, or of different types of identity provider.

Beginning with version 0.6.0, SSSD maintains a separate database file for each domain. This means that each domain has its own cache, and in the event that problems occur and maintenance is necessary, it is very easy to purge the cache for a single domain, by stopping sssd and deleting the corresponding cache file. These cache files are stored in the /var/lib/sss/db/ directory.

All cache files are named according to the domain that they represent, for example cache_DOMAINNAME.ldb.

Considerations Associated with Deleting Cache Files
Deleting a domain's cache file can have some unexpected side effects. You should be aware of the following before you proceed:

- Deleting the cache file also deletes all user data (both identification and cached credentials). Consequently, you should not proceed unless you are online and can authenticate with your username against the domain's servers, because offline authentication will fail.
• If you are online and change your configuration to reference a different identity provider, SSSD will recognize users from both providers until the cached entries from the original provider time out.

To avoid this situation, you can either purge the cache or use a different domain name for the new provider (this is the recommended practice). Changing the domain name means that when you restart SSSD it will create a new cache file (with the new name) and the old file will be ignored.

8.2.2.4. Support for LDAP Referrals
SSSD supports two types of LDAP referrals: object-level referrals and subtree referrals. These referral types and the extent of SSSD support is outlined below.

8.2.2.4.1. Object-level Referrals
SSSD provides full support for object-level referrals within the same LDAP server, correctly handling any differences in the distinguished name (DN) that might exist as part of the LDAP server referral configuration.

SSSD provides partial support for object-level referrals between different LDAP servers, and requires that the full DN of an LDAP request be identical on each server. SSSD does not support referrals to different DN paths on other servers.

8.2.2.4.2. Subtree Referrals
SSSD provides a similar level of support for subtree referrals as it does for object-level referrals. That is, it supports referrals to a changed DN on the local system or to an identical DN on a remote system. The difference with subtree referrals, however, is the ability to set up identical subtrees on each LDAP server and to then configure referrals between these subtrees.

8.2.2.4.3. Enabling LDAP Referrals
To take advantage of the SSSD LDAP referral functionality, you need to set the `ldap_referrals` option to TRUE in the LDAP domain configuration section of the `/etc/sssd/sssd.conf` file. This will enable anonymous access to the second LDAP server.

Note
SSSD only supports LDAP referrals when it is compiled with OpenLDAP version 2.4.13 or later.

8.2.2.5. Differentiating Like-named Users
SSSD supports the differentiation of like-named users in different domains. For example, you can differentiate the user kate in the `ldap.example.com` domain from the user kate in the `ldap.myhome.com` domain. You can use SSSD to make requests using fully-qualified usernames. If you request information for kate, you will receive the information from whichever domain is listed first in the look-up order. If you request information for kate@ldap.myhome.com, however, you will receive the correct user information.

SSSD also provides a `filter_users` option, which you can use to exclude certain users from being fetched from the database. Refer to the `sssd.conf(5)` manual page for full details about this option.

8.2.2.6. Integration with IPA
Beyond the offline authentication, multiple domain management and other features already described, SSSD is also designed to integrate with and enhance the functionality of IPA clients.
environment with the latest version of IPA installed, SSSD provides additional functionality, including support for dynamic DNS updates, host-based access control, and password migration from an LDAP-only environment into the LDAP/Kerberos 5 environment employed by IPA.

8.2.2.6.1. Support for Dynamic DNS Updates
Because the IP address of IPA clients can change, SSSD provides the ability to dynamically update the client's DNS entry on the IPA server. Using a combination of Kerberos and GSS-TSIG (Generic Security Service Algorithm for Secret Key Transaction), IPA can determine the identity of the host machine, authenticate it, and allow that machine to edit its own DNS record. These changes are then stored in the LDAP back end.

Note
Using this authentication system means that each IPA client can only edit its own DNS record; it cannot edit the DNS record of any other client.

Setting up Dynamic DNS Updates
The SSSD configuration file provides two options used for setting up dynamic DNS updates: `ipa_dyndns_update`, used to enable dynamic DNS updates; and `ipa_dyndns_iface`, which specifies the interface whose IP address should be used for dynamic DNS updates.

Refer to the `sssd-ipa` manual page for more information about these options, and how to configure dynamic DNS updates.

Note
Support for dynamic DNS updates is only available on IPA version 2 or later, and with DNS correctly configured.

8.2.3. Setting Up SSSD
This section describes how to install SSSD, how to run the service, and how to configure it for each type of supported information provider.

8.2.3.1. Installing SSSD
Run the following command to install SSSD and any dependencies, including the SSSD client:

```
# yum install sssd
```

SSSD requires very few dependencies and should install very quickly, depending on the speed of your network connection.

8.2.3.1.1. Upgrading from a Previous Version

Upgrading Using RPM Packages
If you are upgrading using RPM packages, the script will run automatically when you upgrade to the new version. This will upgrade the `/etc/sssd/sssd.conf` file to the new format, and copy the existing version to `/etc/sssd/sssd.conf.bak`.

98
Upgrading Manually

It may be necessary to run the upgrade script manually, either because you built SSSD from source files, or because you are using a platform that does not support the use of RPM packages. The synopsis for the script is as follows:

```
upgrade_config.py [-f INFILE] [-o OUTFILE] [-verbose] [-no-backup]
```

- `-f INFILE` — the configuration file to upgrade. If not specified, this defaults to `/etc/sssd/sssd.conf`
- `-o OUTFILE` — the name of the upgraded configuration file. If not specified, this defaults to `/etc/sssd/sssd.conf`
- `-verbose` — produce more verbose output during the upgrade process
- `-no-backup` — do not produce a back-up file. If not specified, this defaults to `INFILE.bak`

### 8.2.3.1.2. Starting and Stopping SSSD

**Note**

Before you start SSSD for the first time, you need to configure at least one domain. Refer to Section 8.2.5, “Configuring Domains” for information on how to configure an SSSD domain.

You can use either the `service` command or the `/etc/init.d/sssd` script to control SSSD. For example, run the following command to start `sssd`:

```
# service sssd start
```

By default, SSSD is configured not to start automatically. There are two ways to change this behavior; if you use the Authentication Configuration tool to configure SSSD, it will reconfigure the default behavior so that SSSD starts when the machine boots. Alternatively, you can use the `chkconfig` command, as follows:

```
# chkconfig sssd on
```

### 8.2.3.2. Configuring SSSD

The global configuration of SSSD is stored in the `/etc/sssd/sssd.conf` file. This file consists of various sections, each of which contains a number of key/value pairs. Some keys accept multiple values; use commas to separate multiple values for such keys. This configuration file uses data types of string (no quotes required), integer and Boolean (with values of `TRUE` or `FALSE`). Comments are indicated by either a hash sign (#) or a semicolon (;) in the first column. The following example illustrates some of this syntax:

```
[<section>]
# Keys with single values
key1 = value
key2 = val2

# Keys with multiple values
key10 = val10,val11
```
Chapter 8. Authentication Configuration

**Note**

You can use the `-c` (or `--config`) parameter on the command line to specify a different configuration file for SSSD.

The format of the configuration file is described in *Section 8.2.8, “SSSD Configuration File Format”*. Refer to the `sssd.conf(5)` manual page for more information on global SSSD configuration options.

### 8.2.3.2.1. Configuring NSS

SSSD provides a new NSS module, `sssd_nss`, so that you can configure your system to use SSSD to retrieve user information. Edit the `/etc/nsswitch.conf` file for your system to use the `sss` name database. For example:

```
passwd: files sss
group: files sss
```

### 8.2.3.2.2. Configuring PAM

**Warning**

Use extreme care when changing your PAM configuration. A mistake in the PAM configuration file can lock you out of the system completely. Always back up your configuration files before performing any changes, and keep a session open so that you can revert any changes you make should the need arise.

To enable your system to use SSSD for PAM, you need to edit the default PAM configuration file. On Red Hat Enterprise Linux—based systems, this is the `/etc/pam.d/system-auth` file. Edit this file to reflect the following example, and then restart `sssd`:

```
# %PAM-1.0
# This file is auto-generated.
# User changes will be destroyed the next time authconfig is run.
auth        required      pam_env.so
auth        sufficient    pam_unix.so nullok try_first_pass
auth        requisite     pam_succeed_if.so uid >= 500 quiet
auth        sufficient    pam_sss.so use_first_pass
auth        required      pam_deny.so

account     required      pam_unix.so broken_shadow
account     sufficient    pam_localuser.so
account     sufficient    pam_succeed_if.so uid < 500 quiet
account [default=bad success=ok user_unknown=ignore] pam_sss.so
account     required      pam_permit.so

password    requisite     pam_cracklib.so try_first_pass retry=3
password    sufficient    pam_unix.so sha512 shadow nullok try_first_pass use_authtok
password    sufficient    pam_sss.so use_authtok
password    required      pam_deny.so

session     required      pam_mkhomedir.so umask=0022 skel=/etc/skel/
session     optional      pam_keyinit.so revoke
```
8.2.3.2.2.1. Using Custom Home Directories with SSSD

If your LDAP users have home directories that are not in `/home`, and if your system is configured to create home directories the first time your users log in, then these directories will be created with the wrong permissions. For example, instead of a typical home directory such as `/home/<username>`, your users might have home directories that include their locale, such as `/home/<locale>/ <username>`. If this is true for your system, the following steps need to be taken (preemptively):

1. Apply the correct SELinux context and permissions from the `/home` directory to the home directory that you use on your system. In the example above, the following command would achieve this result (replace the directory names with those that apply to your system):

   # semanage fcontext -a -e /home /home/locale

2. Ensure the `oddjob-mkhomedir` package is installed on your system and then re-run the Authentication Configuration tool.

   This package provides the `pam_oddjob_mkhomedir.so` library, which the Authentication Configuration tool will then use to create your custom home directories. You need to use this library to create your home directories, and not the default `pam_mkhomedir.so` library, because the latter cannot create SELinux labels.

   **Note**

   The Authentication Configuration tool will automatically use the `pam_oddjob_mkhomedir.so` library if it is available. Otherwise, it will default to using `pam_mkhomedir.so`.

If the preceding steps were not performed before the custom home directories were created, you can use the following commands to correct the permissions and SELinux contexts (again, replace the directory names with those that apply to your system):

   # semanage fcontext -a -e /home /home/locale
   # restorecon -R -v /home/locale

8.2.3.2.2.2. Using "include" Statements in PAM Configurations

Recent PAM implementations allow you to use `include` statements in PAM configurations. For example:

```plaintext
... session     include      system-auth
session     optional     pam_console.so
...```
Chapter 8. Authentication Configuration

8.2.3.2.3. Configuring Access Control
SSSD provides a rudimentary access control mechanism, offering two solutions based on the value of the access_provider option in the [domain/<NAME>] section in the /etc/sssd/sssd.conf file.

8.2.3.2.3.1. The Simple Access Provider
The first of these solutions is known as the Simple Access Provider, and is based on the implementation of access or deny lists of usernames. To enable the Simple Access Provider, you need to set the access_provider option to simple, and then add usernames as a comma-separated list to either the simple_allow_users or simple_deny_users options.

Using the Simple Access Provider
By using the Simple Access Provider, you can continue to support a number of network logins to maintain common network accounts on company or department laptops, but you might want to restrict the use of a particular laptop to one or two users. This means that even if a different user authenticated successfully against the same authentication provider, the Simple Access Provider would prevent that user from gaining access.

The following example demonstrates the use of the Simple Access Provider to grant access to two users. This example assumes that SSSD is correctly configured and example.com is one of the domains specified in the [sssd] section, and only shows the Simple Access Provider-specific options.

```
[domain/example.com]
access_provider = simple
simple_allow_users = user1, user2
```

Access Control Rules
The Simple Access Provider adheres to the following three rules to determine which users should or should not be granted access:

- If both lists are empty, access is granted.
- If simple_allow_users is set, only users from this list are allowed access. This setting supersedes the simple_deny_users list (which would be redundant).
- If the simple_allow_users list is empty, users are allowed access unless they appear in the simple_deny_users list.

Note
In the preceding example, if a sufficient condition from system-auth returns PAM_SUCCESS, pam_console.so will not be executed.

Note
The Local ID provider does not support simple as an access provider.
Important

Defining both `simple_allow_users` and `simple_denial_users` is a configuration error. If this occurs, SSSD will output an error to the `/var/log/sssd/sssd_default.log` log file when loading the back end, but continue to start normally. Future versions of SSSD will output an error and fail to start.

8.2.3.2.3.2. The LDAP Access Provider

The second access control solution uses the LDAP server itself as the access provider (`access_provider=ldap`) and the associated filter option (`ldap_access_filter`) to specify which users are granted access to the specified host. Note that these two options are codependent; if you use LDAP as your access provider then you must specify a value for the `ldap_access_filter` option, otherwise all users will be denied access. If you are not using LDAP as your access provider, then the `ldap_access_filter` option has no effect.

Using the LDAP Access Provider

The following example demonstrates the use of the LDAP Access Provider to grant access to members of the "allowedusers" group in LDAP. This example assumes that SSSD is correctly configured and example.com is one of the domains specified in the `[sssd]` section, and only shows the LDAP Access Provider-specific options.

```
[domain/example.com]
access_provider = ldap
ldap_access_filter = memberOf=cn=allowedusers,ou=Groups,dc=example,dc=com
```

Note

Offline caching for this feature is limited to determining whether or not the user's last online login attempt was successful. If they were granted access during their last login, they will continue to be granted access while offline, and vice-versa.

Refer to the `sssd-ldap` manual page for more information about using the LDAP Access Provider.

8.2.3.2.4. Configuring Failover

The failover feature allows back ends to automatically switch to a different server if the primary server fails. These servers are entered as a case-insensitive, comma-separated list in the `[domain/<NAME>]` sections of the `/etc/sssd/sssd.conf` file, and listed in order of preference. This list can contain any number of servers.

For example, if you have configured a native LDAP domain, you could specify the following as your `ldap_uri` values:

```
ldap_uri = ldap://ldap0.mydomain.org, ldap://ldap1.mydomain.org, ldap://ldap2.mydomain.org
```

In this configuration, `ldap://ldap0.mydomain.org` functions as the primary server. If this server fails, the SSSD failover mechanism first attempts to connect to `ldap1.mydomain.org`, and if that server is unavailable, it then attempts to connect to `ldap2.mydomain.org`. 
If the parameter that specifies which server to connect to for the specific domain (for example, `ldap_uri`, `krb5_kdcip`, ...) is not specified, the back end defaults to using use service discovery. Refer to Section 8.2.3.2.4.1, “Using SRV Records with Failover” for more information on service discovery.

**Important**

Do not use multiple `ldap_uri` parameters to specify your failover servers. The failover servers must be entered as a comma-separated list of values for a single `ldap_uri` parameter. If you enter multiple `ldap_uri` parameters, SSSD only recognizes the last entry.

Future versions of SSSD will throw an error upon receiving additional `ldap_uri` entries.

### 8.2.3.2.4.1. Using SRV Records with Failover

SSSD also supports the use of SRV records in its failover configuration. This means that you can specify a server that is later resolved into a list of specific servers using SRV requests. The `priority` and `weight` attributes of SRV records provide further opportunity for specifying which servers should be contacted first in the event that the primary server fails.

For every service with which you want to use service discovery, you need to add a special DNS record to your DNS server using the following form:

```
_service._protocol._domain TTL priority weight port hostname
```

A typical configuration would contain multiple such records, each with a different priority (for failover) and different weights (for load balancing).

The client then makes an SRV DNS query to retrieve a list of host names, their priorities, and weights. These queries are of the form `_service._protocol._domain`, for example, `_ldap._tcp._redhat.com`. The client then sorts this list according to the priorities and weights, and connects to the first server in this sorted list.

For more information on SRV records, refer to RFC 2782.

### 8.2.3.2.4.2. How the Failover Mechanism Works

The failover mechanism distinguishes between machines and services. The back end first tries to resolve the hostname of a given machine; if this resolution attempt fails, the machine is considered offline. No further attempts are made to connect to this machine for any other service. If the resolution attempt succeeds, the back end tries to connect to a service on this machine. If the service connection attempt fails, then only this particular service is considered offline and the back end automatically switches over to the next service. The machine is still considered online and might still be tried for another service.

The failover mechanism does not handle DNS A records with multiple IP addresses; instead it only uses the first address. DNS round-robin cannot be used for failover. Further, providing multiple A records does not provide failover. Only the first A record is used, and if a lookup attempt on the first record fails then the system attempts no further lookups. To find multiple servers with a single request, and thus implementing failover, SSSD relies on SRV resource records, as explained in Section 8.2.3.2.4.1, “Using SRV Records with Failover”.

---

Further connection attempts are made to machines or services marked as offline after a specified period of time; this is currently hard coded to 30 seconds. If there are no more machines to try, the back end as a whole switches to offline mode, and then attempts to reconnect every 30 seconds.

8.2.4. Configuring Services

Individual pieces of SSSD functionality are provided by special SSSD services that are started and stopped together with SSSD. The services provided by SSSD have their own configuration sections. The [sssd] section also lists the services that are active and should be started when sssd starts within the services directive.

SSSD currently provides several services:

- **NSS** — An NSS provider service that answers NSS requests from the sssd_nss module.
- **PAM** — A PAM provider service that manages a PAM conversation through the sssd_pam PAM module.
- **monitor** — A special service that monitors all other SSSD services, and starts or restarts them as needed. Its options are specified in the [sssd] section of the /etc/sssd/sssd.conf configuration file.

8.2.4.1. Configuration Options

The following sections cover the most important SSSD configuration options. Refer to the sssd.conf(5) manual page that ships with SSSD for information on all the available configuration options.

8.2.4.1.1. General Configuration Options

- **debug_level (integer)**

  Sets the debug level for a particular service. This is a per-service setting (that is, it can appear in any of the [service/<NAME>] sections in the SSSD configuration file).

- **reconnection_retries (integer)**

  In the event of a data provider crash or restart, this specifies the number of times that a service should attempt to reconnect.

  **Note**

  If a DNS lookup fails to return an IPv4 address for a hostname, SSSD attempts to look up an IPv6 address before returning a failure. Note that this only ensures that the async resolver identifies the correct address; there is currently a bug in the LDAP code that prevents SSSD from connecting to an LDAP server over IPv6. This is being investigated separately.

8.2.4.1.2. NSS Configuration Options

Use the following options to configure the Name Service Switch (NSS) service. Refer to the sssd.conf(5) manual page for full details about each option.

- **enum_cache_timeout (integer)**
Chapter 8. Authentication Configuration

Specifies for how long (in seconds) `sssd_nss` should cache enumerations (requests for information about all users).

- **entry_cache_nowait_percentage (integer)**
  
  Specifies for how long `sssd_nss` should return cached entries before initiating an out-of-band cache refresh (0 disables this feature).

  You can configure the entry cache to automatically update entries in the background if they are requested beyond a percentage of the `entry_cache_timeout` value for the domain.

  Valid values for this option are 0-99, and represent a percentage of the `entry_cache_timeout` value for each domain.

- **entry_negative_timeout (integer)**
  
  Specifies for how long (in seconds) `sssd_nss` should cache negative cache hits (that is, queries for invalid database entries, such as nonexistent ones) before asking the back end again.

- **filter_users, filter_groups (string)**
  
  Exclude certain users from being fetched from the sss NSS database. This is particularly useful for system accounts such as `root`.

- **filter_users_in_groups (Boolean)**
  
  If set to `TRUE`, specifies that users listed in the `filter_users` list do not appear in group memberships when performing group lookups. If set to `FALSE`, group lookups return all users that are members of that group. If not specified, defaults to `TRUE`.

8.2.4.1.3. PAM Configuration Options

Use the following options to configure the Pluggable Authentication Module (PAM) service.

- **offline_credentials_expiration (integer)**
  
  If the authentication provider is offline, specifies for how long to allow cached log-ins (in days). This value is measured from the last successful online log-in. If not specified, defaults to 0 (no limit).

- **offline_failed_login_attempts (integer)**
  
  If the authentication provider is offline, specifies how many failed log in attempts are allowed. If not specified, defaults to 0 (no limit).

- **offline_failed_login_delay (integer)**
  
  Specifies the time in minutes after the value of `offline_failed_login_attempts` has been reached before a new log in attempt is possible.

  If set to 0, the user cannot authenticate offline if the value of `offline_failed_login_attempts` has been reached. Only a successful online authentication can re-enable offline authentication. If not specified, defaults to 5.

8.2.5. Configuring Domains

A domain is a database of user information. SSSD can use more than one domain at the same time, but at least one must be configured for SSSD to start. Using SSSD domains, it is possible to use
several LDAP servers providing several unique namespaces. You can specify not only where users’ identity information is stored, but how users authenticate against each of the specified domains.

SSSD supports the following identity and authentication combinations:

- **LDAP/LDAP**
  This combination uses an LDAP back end as both the identity and authentication provider.

- **LDAP/KRB5**
  This combination uses an LDAP back end as the identity provider, and uses Kerberos to provide authentication.

- **proxy**
  Specifying a proxy identity or authentication provider uses an existing NSS library or customized PAM stack, but takes advantage of the SSSD caching mechanism.

The following example assumes that SSSD is correctly configured and FOO is one of the domains in the [sssd] section. This example shows only the configuration of Kerberos authentication; it does not include any identity provider.

```
[domain/FOO]
auth_provider = krb5
krb5_kdcip = 192.168.1.1
krb5_realm = EXAMPLE.COM
```

**8.2.5.1. Domain Configuration Options**
You can add new domain configurations to the [domain/<NAME>] sections of the `/etc/sssd/sssd.conf` file, and then add the list of domains to the domains attribute of the [sssd] section, in the order you want them to be queried.

**8.2.5.1.1. General Domain Configuration Options**
You can use the following configuration options in a domain configuration section:

- **min_id,max_id (integer)**
  Specifies the UID and GID limits for the domain. If a domain contains entries that are outside these limits, they are ignored.

  The default value for min_id is 1; the default value for max_id is 0 (unbounded).
Chapter 8. Authentication Configuration

**Important**

If `min_id` is unspecified, it defaults to 1 for any back end. This default was chosen to provide compatibility with existing systems and to ease any migration attempts. LDAP administrators should be aware that granting identities in this range may conflict with users in the local /etc/passwd file. To avoid these conflicts, `min_id` should be set to 1000 or higher wherever possible.

The `min_id` option determines the minimum acceptable value for both UID and GID numbers. Accounts with either UID or GID values below the `min_id` value are filtered out and not made available on the client.

- **enumerate (Boolean)**

  Specifies whether or not to enumerate (list) the users and groups of a domain.

  Enumeration means that the entire set of available users and groups on the remote source is cached on the local machine. When enumeration is disabled, users and groups are only cached as they are requested. For performance reasons, it is recommended that you disable enumeration for domains with many users and groups.

  The default value for this parameter is **FALSE**. Set this value to **TRUE** to enable enumeration of users and groups of a domain.

- **timeout (integer)**

  Specifies the timeout in seconds for this particular domain.

  This is used to ensure that the backend process is alive and capable of answering requests. The default value for this parameter is 10 seconds. Raising this timeout might prove useful for slower back ends, such as distant LDAP servers.

  **Note**

  If you set `timeout = 0`, SSSD reverts to the default value; you cannot force a timeout value of zero, because this would force the sssd daemon into a loop.

- **cache_credentials (Boolean)**

  Specifies whether or not to store user credentials in the local SSSD domain database cache.

  The default value for this parameter is **FALSE**. You should set this value to **TRUE** for domains other than local if you want to enable offline authentication.

- **id_provider (string)**

  Specifies the data provider identity back end to use for this domain. Currently supported identity back ends are:
  - proxy — Support a legacy NSS provider (for example, nss_nis).
SSSD needs to know which legacy NSS library to load in order to start successfully. If you set `id_provider` to `proxy`, ensure that you also specify a value for `proxy_lib_name`. Refer to Section 8.2.5.4, “Configuring a Proxy Domain” for information on this attribute.

- **local** — SSSD internal local provider.
- **ldap** — LDAP provider.

**entry_cache_timeout (integer)**

Specifies for how long the domain's data provider should cache positive cache hits (that is, queries for valid database entries) before asking the database again.

**use_fully_qualified_names (Boolean)**

Specifies whether or not requests to this domain require fully-qualified domain names.

If set to `TRUE`, all requests to this domain must use fully-qualified domain names. It also means that the output from the request displays the fully-qualified name.

The ability to restrict requests in this way means that if you know you have multiple domains with conflicting usernames, then there is no doubt about which username the query will resolve.

Consider the following examples, in which the IPA domain database contains a user named `ipauser01`, and the `use_fully_qualified_names` attribute is set to `TRUE`:

```
# getent passwd ipauser01
[no output]
# getent passwd ipauser01@IPA
ipauser01@IPA:x:937315651:937315651:ipauser01:/home/ipauser01:/bin/sh
```

In the following examples, using the same IPA domain and user, the `use_fully_qualified_names` attribute is set to `FALSE`:

```
# getent passwd ipauser01
ipauser01:x:937315651:937315651:ipauser01:/home/ipauser01:/bin/sh
# getent passwd ipauser01@IPA
ipauser01:x:937315651:937315651:ipauser01:/home/ipauser01:/bin/sh
```

If `use_fully_qualified_names` is set to `FALSE`, you can continue to use the fully-qualified name in your requests, but only the simplified version is displayed in the output.

SSSD can only parse `name@domain`, not `name@realm`. You can, however, use the same name for both your domain and your realm.
Chapter 8. Authentication Configuration

• auth_provider (string)

The authentication provider used for the domain. The default value for this option is the value of id_provider if it is set and can handle authentication requests.

Currently supported authentication providers are:

• ldap — for native LDAP authentication. Refer to the sssd-ldap(5) manual page for more information on configuring LDAP.

• krb5 — for Kerberos authentication. Refer to the sssd-krb5(5) manual page for more information on configuring Kerberos.

• proxy — for relaying authentication to some other PAM target.

• none — explicitly disables authentication.

8.2.5.1.2. Proxy Configuration Options

• proxy_pam_target (string)

This option is only used when the auth_provider option is set to proxy, and specifies the target to which PAM must proxy.

This option has no default value. If proxy authentication is required, you need to specify your own PAM target. This corresponds to a file containing PAM stack information in the system's default PAM configuration directory. On Red Hat Enterprise Linux-based systems, this is the /etc/pam.d/ directory.

• proxy_lib_name (string)

This option is only used when the id_provider option is set to proxy, and specifies which existing NSS library to proxy identity requests through.

This option has no default value. You need to manually specify an existing library to take advantage of this option. For example, set this value to nis to use the existing libnss_nis.so file.

8.2.5.2. Configuring an LDAP Domain

An LDAP domain is one where the id_provider option is set to ldap (id_provider = ldap).

Such a domain requires a running LDAP server against which to authenticate. This can be an open source LDAP server such as OpenLDAP or Microsoft Active Directory. SSSD currently supports Microsoft Active Directory 2003 (+Services For UNIX) and Active Directory 2008 (+Subsystem for UNIX-based applications). In all cases, the client configuration is stored in the /etc/sssd/sssd.conf file.

How to Authenticate Against an LDAP Server

SSSD does not support authentication over an unencrypted channel. Consequently, if you want to authenticate against an LDAP server, either TLS/SSL, LDAPS, or LDAP+GSSAPI is required. If the LDAP server is used only as an identity provider, an encrypted channel is not needed.

Edit your /etc/sssd/sssd.conf file to reflect the following example:

```
# A native LDAP domain
[domain/LDAP]
enumerate = false
cache_credentials = TRUE
```
Configuring Domains

id_provider = ldap
auth_provider = ldap
ldap_schema = rfc2307
chpass_provider = ldap
ldap_uri = ldap://ldap.mydomain.org
ldap_search_base = dc=mydomain,dc=org
tls_reqcert = demand
ldap_tls_cacert = /etc/pki/tls/certs/ca-bundle.crt

Selecting an LDAP Schema

You can set the `ldap_schema` attribute to either rfc2307 or rfc2307bis. These schema define how groups in LDAP are specified. In RFC 2307, group objects use a multi-valued attribute, memberuid, which lists the names of the users that belong to that group. In RFC 2307bis, instead of the memberuid, group objects use the member attribute. Rather than just the name of the user, this attribute contains the full Distinguished Name (DN) of another object in the LDAP database. This means that groups can have other groups as members. That is, it adds support for nested groups.

SSSD assumes that your LDAP server is using RFC 2307. If your LDAP server is using RFC 2307bis, and you do not update the `/etc/sssd/sssd.conf` file accordingly, this can impact how your users and groups are displayed. It also means that some groups will not be available and network resources may be inaccessible even though you have permissions to use them.

For example, when using RFC 2307bis and you have configured both primary and secondary groups, or are using nested groups, you can use the `id` command to display these groups:

```
[f12server@ipaserver ~]$ id
uid=500(f12server) gid=500(f12server) groups=500(f12server),510(f12tester)
```

If instead you have configured your client to use RFC 2307 then only the primary group is displayed.

Changes to this setting only affect how SSSD determines the groups to which a user belongs; there is no negative effect on the actual user data. If you do not know the correct value for this attribute, consult your System Administrator.

Specifying Timeout Values

SSSD supports a number of timeout values that apply when configuring an LDAP domain. These are described below.

- **ldap_search_timeout (integer)** — Specifies the timeout (in seconds) that LDAP searches are allowed to run before they are cancelled and cached results are returned (and offline mode is entered). If not specified:
  
  Defaults to five when `enumerate = False`

  Defaults to 30 when `enumerate = True`. This option is forced to a minimum of 30 in this case.

  **Note**

  This option is subject to change in future versions of SSSD, where it may be replaced by a series of timeouts for specific look-up types.
8.2.5.3. Configuring a Microsoft Active Directory Domain

You can configure SSSD to use Microsoft Active Directory as an LDAP back end, providing both identity and authentication services. If you are using Active Directory 2003, SSSD requires that you install Windows Services for UNIX (SFU) on the machine where Active Directory is installed. If instead you are using Active Directory 2008, you need to install the Subsystem for UNIX-based Applications (SUA) on the Active Directory machine.

**Note**

SFU is not supported on 64-bit operating systems. Refer to [http://support.microsoft.com/kb/920751](http://support.microsoft.com/kb/920751) for more information about which Windows systems can provide a suitable platform for an SSSD LDAP back end.

8.2.5.3.1. Configuring Active Directory 2003 as an LDAP Back End

The example /etc/sssd/sssd.conf file that ships with SSSD contains the following sample configuration for Active Directory 2003:

```ini
# Example LDAP domain where the LDAP server is an Active Directory 2003 server.
[domain/AD]
description = LDAP domain with AD server
enumerate = false
min_id = 1000
; id_provider = ldap
auth_provider = ldap
ldap_uri = ldap://your.ad.server.com
ldap_schema = rfc2307bis
ldap_search_base = dc=example,dc=com
ldap_default_bind_dn = cn=Administrator,cn=Users,dc=example,dc=com
ldap_default_authtok_type = password
ldap_default_authtok = YOUR_PASSWORD
ldap_user_object_class = person
ldap_user_name = msSFU30Name
ldap_user_uid_number = msSFU30UidNumber
ldap_user_gid_number = msSFU30GidNumber
ldap_user_home_directory = msSFU30HomeDirectory
ldap_user_shell = msSFU30LoginShell
ldap_user_principal = userPrincipalName
ldap_group_object_class = group
ldap_group_name = msSFU30Name
ldap_group_gid_number = msSFU30GidNumber
```
This configuration is specific to Windows Active Directory 2003. Refer to Section 8.2.5.3.2, “Configuring Active Directory 2003 R2 and 2008 as LDAP Back Ends” for information on how to configure Active Directory 2003 R2 and Active Directory 2008.

The above configuration assumes that the certificates are stored in the default location (that is, in `/etc/openldap/cacerts`) and that the `c_rehash` function has been used to create the appropriate symlinks.

Refer to the `sssd-ldap(5)` manual page for a full description of all the options that apply to LDAP domains.

8.2.5.3.2. Configuring Active Directory 2003 R2 and 2008 as LDAP Back Ends

The configuration of `/etc/sssd/sssd.conf` to support Active Directory 2003 R2 or Active Directory 2008 as a back end is similar to that for AD 2003. The following example configuration highlights the necessary changes.

```
# Example LDAP domain where the LDAP server is an Active Directory 2003 R2 or an Active Directory 2008 server.

[domain/AD]
description = LDAP domain with AD server
; debug_level = 9
enumerate = false

id_provider = ldap
auth_provider = ldap
chpass_provider = ldap

ldap_uri = ldap://your.ad.server.com
ldap_tls_cacertdir = /etc/openldap/cacerts
ldap_tls_cacert = /etc/openldap/cacerts/test.cer
ldap_search_base = dc=example,dc=com
ldap_default_bind_dn = cn=Administrator,cn=Users,dc=example,dc=com
ldap_default_authtok_type = password
ldap_default_authtok = YOUR_PASSWORD
ldap_pwd_policy = none
ldap_user_object_class = user
ldap_group_object_class = group
```

The above configuration assumes that the certificates are stored in the default location (that is, in `/etc/openldap/cacerts`) and that the `c_rehash` function has been used to create the appropriate symlinks.
8.2.5.4. Configuring a Proxy Domain

SSSD currently only supports LDAP and Kerberos as authentication providers. If you prefer to use SSSD (for example, to take advantage of its caching functionality), but SSSD does not support your authentication method, you can set up a proxy authentication provider. This could be the case if you use fingerprint scanners or smart cards as part of your authentication process.

- **proxy_pam_target** (string)
  
  This option is only used when the `auth_provider` option is set to `proxy`, and specifies the proxy target that PAM proxies to.

  This option has no default value. If proxy authentication is required, you need to specify your own PAM target. This corresponds to a file containing PAM stack information in the system's default PAM configuration directory. On Red Hat Enterprise Linux—based systems, this is the `/etc/pam.d/` directory.

  Important

  Ensure that your proxy PAM stack does not recursively include `pam_sss.so`.

- **proxy_lib_name** (string)

  This option is only used when the `id_provider` option is set to `proxy`, and specifies which existing NSS library to proxy identity requests through.

  This option has no default value. You need to manually specify an existing library to take advantage of this option. For example, set this value to `nis` to use the existing `libnss_nis.so` file.

8.2.6. Setting Up Kerberos Authentication

In order to set up Kerberos authentication, you need to know the address of your key distribution center (KDC) and the Kerberos domain. The client configuration is then stored in the `/etc/sssd/sssd.conf` file.

The Kerberos 5 authentication back end does not contain an identity provider and must be paired with one in order to function properly (for example, `id_provider = ldap`). Some information required by the Kerberos 5 authentication back end must be supplied by the identity provider, such as the user's Kerberos Principal Name (UPN). The identity provider configuration should contain an entry to specify this UPN. Refer to the manual page for the applicable identity provider for details on how to configure the UPN.

If the UPN is not available in the identity back end, SSSD will construct a UPN using the format `username@krb5_realam`.

SSSD assumes that the Kerberos KDC is also a Kerberos kadmin server. However, it is very common for production environments to have multiple, read-only replicas of the KDC, but only a single kadmin server (because password changes and similar procedures are comparatively rare). To manage this type of configuration, you can use the `krb5_kpasswd` option to specify where your password changing service is running, or if it is running on a non-default port. Refer to the `sssd-krb5(5)` manual page for more information about this and all Kerberos configuration options.
How to Set Up Kerberos Authentication

Edit your `/etc/sssd/sssd.conf` file to reflect the following example:

```
# A domain with identities provided by LDAP and authentication by Kerberos
[domain/KRBDOMAIN]
enumerate = false
id_provider = ldap
chpass_provider = krb5
ldap_uri = ldap://ldap.mydomain.org
ldap_search_base = dc=mydomain,dc=org
tls_reqcert = demand
ldap_tls_cacert = /etc/pki/tls/certs/ca-bundle.crt

auth_provider = krb5
krb5_kdcip = 192.168.1.1
krb5.realm = EXAMPLE.COM
krb5_changepw_principal = kadmin/changepw
krb5_ccachedir = /tmp
krb5_ccname_template = FILE:%d/krb5cc_%U_XXXXXX
krb5_auth_timeout = 15
```

This example describes the minimum options that must be configured when using Kerberos authentication. Refer to the `sssd-krb5(5)` manual page for a full description of all the options that apply to configuring Kerberos authentication.

8.2.7. Troubleshooting

This section lists some of the issues you may encounter when implementing SSSD, the possible causes of these issues, and how to resolve them. If you find further issues that are not covered here, refer to the `We Need Feedback` section in the Preface for information on how to file a bug report.

8.2.7.1. Using SSSD Log Files

SSSD uses a number of log files to report information about its operation, and this information can help to resolve issues in the event of SSSD failure or unexpected behavior. The default location for these log files on Red Hat Enterprise Linux—based systems is the `/var/log/sssd/` directory.

SSSD produces a log file for each back end (that is, one log file for each domain specified in the `/etc/sssd/sssd.conf` file), as well as an `sssd_pam.log` and an `sssd_nss.log` file. This level of granularity can help you to quickly isolate and resolve any errors or issues you might experience with SSSD.

You should also examine the `/var/log/secure` file, which logs authentication failures and the reason for the failure. For example, if you see Reason 4: System Error reported against any failure, you should increase the debug level of the log files.

Producing More Verbose Log Files

If you are unable to identify and resolve any problems with SSSD after inspection of the default log files, you can configure SSSD to produce more verbose files. You can set the `debug_level` option in the `/etc/sssd/sssd.conf` for the domain that is causing concern, and then restart SSSD. Refer to the `sssd.conf(5)` manual page for more information on how to set the `debug_level` for a specific domain.

All log files include timestamps on debug messages by default. This can make it easier to understand any errors that may occur, why they occurred, and how to address them. If necessary, you can disable these timestamps by setting the appropriate parameter to `FALSE` in the `/etc/sssd/sssd.conf` file:
Chapter 8. Authentication Configuration

8.2.7.2. Problems with SSSD Configuration

• SSSD fails to start

• SSSD requires at least one properly configured domain before the service will start. Without such a domain, you might see the following error message when trying to start SSSD with the following command:

```
# sssd -d4
```

[sssd] [ldb] (3): server_sort:Unable to register control with rootdse!

[sssd] [confdb_get_domains] (0): No domains configured, fatal error!

[sssd] [get_monitor_config] (0): No domains configured.

You can ignore the "Unable to register control with rootdse!" message, as it is erroneous. The other messages, however, indicate that SSSD is unable to locate any properly configured domains.

Edit your `/etc/sssd/sssd.conf` file and ensure you have at least one properly configured domain, and then try to start SSSD.

• SSSD requires at least one available service provider before it will start. With no available service providers, you might see the following error message when trying to start SSSD with the following command:

```
# sssd -d4
```

[sssd] [ldb] (3): server_sort:Unable to register control with rootdse!

[sssd] [get_monitor_config] (0): No services configured!

You can ignore the "Unable to register control with rootdse!" message, as it is erroneous. The other message, however, indicates that SSSD is unable to locate any available service providers.

Edit your `/etc/sssd/sssd.conf` file and ensure you have at least one available service providers, and then try to start SSSD.

**Important**

SSSD requires that service providers be configured as a comma-separated list in a single `services` entry in the `/etc/sssd/sssd.conf` file. If services are listed in multiple entries, only the last entry is recognized by SSSD.

• Refer to the `sssd.conf(5)` manual page for more options that might assist in troubleshooting issues with SSSD.
8.2.7.3. Problems with SSSD Service Configuration

8.2.7.3.1. Problems with NSS
This section describes some common problems with NSS, their symptoms, and how to resolve them.

• NSS fails to return user information

  • Ensure that NSS is running

    # service sssd status

    This command should return results similar to the following:

    sssd (pid 21762) is running...

  • Ensure that you have correctly configured the [nss] section of the /etc/sssd/sssd.conf file. For example, ensure that you have not misconfigured the filter_users or filter_groups attributes. Refer to the NSS configuration options section of the sssd.conf(5) manual page for information on how to configure these attributes.

  • Ensure that you have included nss in the list of services that sssd should start

  • Ensure that you have correctly configured the /etc/nsswitch.conf file. Refer to the section Section 8.2.3.2.1, “Configuring NSS” for information on how to correctly configure this file.

8.2.7.3.2. Problems with PAM
This section describes some common problems with PAM, their symptoms, and how to resolve them.

• Setting the password for the local SSSD user prompts twice for the password

  When attempting to change a local SSSD user's password, you might see output similar to the following:

  [root@clientF11 tmp]# passwd user1000
  Changing password for user user1000.
  New password:
  Retype new password:
  New Password:
  Reenter new Password:
  passwd: all authentication tokens updated successfully.

  This is the result of an incorrect PAM configuration. Refer to Section 8.2.3.2.2, “Configuring PAM”, and ensure that the use_authtok option is correctly configured in your /etc/pam.d/system-auth file.

8.2.7.3.3. Problems with NFS and NSCD
SSSD is not designed to be used with the nscd daemon, and will likely generate warnings in the SSSD log files. Even though SSSD does not directly conflict with nscd, the use of both at the same time can result in unexpected behavior (specifically with how long entries are being cached).

If you are using Network Manager to manage your network connections, it may take several minutes for the network interface to come up. During this time, various services will attempt to start. If these services start before the network is up (that is, the DNS servers cannot yet be reached) they will fail to identify the forward or reverse DNS entries they might need. These services will be reading
an incorrect or possibly empty `resolv.conf` file. This file is typically only read once, and so any changes made to this file are not automatically applied.

This can result in the failure of some system services, and in particular can cause NFS locking to fail on the machine where the `nscd` service is running, unless that service is manually restarted.

One method of working around this problem is to enable caching for `hosts` and `services` in the `/etc/nscd.conf` file, and to rely on the SSSD cache for the `passwd` and `group` entries. With `nscd` answering `hosts` and `services` requests, these entries would have been cached and returned by `nscd` during the boot process.

**Note**

Later versions of SSSD should negate any need for NSCD.

### 8.2.7.4. Problems with SSSD Domain Configuration

- NSS returns incorrect user information
  - If your search for user information returns incorrect data, ensure that you do not have conflicting usernames in separate domains. If you use multiple domains, it is recommended that you set the `use_fully_qualified_domains` attribute to `TRUE` in the `/etc/sssd/sssd.conf` file.

### 8.2.7.5. Additional Resources

#### 8.2.7.5.1. Manual Pages

SSSD ships with a number of manual pages, all of which provide additional information about specific aspects of SSSD, such as configuration files, commands, and available options. SSSD currently provides the following manual pages:

- `sssd.conf(5)`
- `sssd-ipa(5)`
- `sssd-krb5(5)`
- `sssd-ldap(5)`
- `sssd(8)`
- `sssd_krb5_locator_plugin(8)`
- `pam_sss(8)`

You should refer to these manual pages for detailed information about all aspects of SSSD, its configuration, and associated tools and commands.

#### 8.2.7.5.2. Mailing Lists

You can subscribe to the SSSD mailing list to follow and become involved in the development of SSSD, or to ask questions about any issues you may be experiencing with your SSSD deployment.

Visit [https://fedorahosted.org/mailman/listinfo/sssd-devel](https://fedorahosted.org/mailman/listinfo/sssd-devel) to subscribe to this mailing list.
8.2.8. SSSD Configuration File Format

The following listing describes the current version (Version 2) of the SSSD configuration file format.

```plaintext
[sssd]
config_file_version = 2
services = nss, pam
domains = mybox.example.com, ldap.example.com, ipa.example.com, nis.example.com
# sibus_timeout = 300

[nss]
nss_filter_groups = root
nss_filter_users = root
nss_entry_cache_timeout = 30
nss_enum_cache_timeout = 30

[domain/mybox.example.com]
domain_type = local
enumerate = true
min_id = 1000
# max_id = 2000
local_default_shell = /bin/bash
local_default_homedir = /home

# Possible overrides
# id_provider = local
# auth_provider = local
# authz_provider = local
# passwd_provider = local

[domain/ldap.example.com]
domain_type = ldap
domain_type = ldap

[domain/nis.example.com]
id_provider = proxy
proxy_lib = nis
auth_provider = proxy
proxy_auth_target = nis_pam_proxy
```
**OpenSSH**

SSH (Secure Shell) is a protocol which facilitates secure communications between two systems using a client/server architecture and allows users to log into server host systems remotely. Unlike other remote communication protocols, such as FTP or Telnet, SSH encrypts the login session, rendering the connection difficult for intruders to collect unencrypted passwords.

The `ssh` program is designed to replace older, less secure terminal applications used to log into remote hosts, such as `telnet` or `rsh`. A related program called `scp` replaces older programs designed to copy files between hosts, such as `rcp`. Because these older applications do not encrypt passwords transmitted between the client and the server, avoid them whenever possible. Using secure methods to log into remote systems decreases the risks for both the client system and the remote host.

Red Hat Enterprise Linux includes the general OpenSSH package (`openssh`) as well as the OpenSSH server (`openssh-server`) and client (`openssh-clients`) packages. Note, the OpenSSH packages require the OpenSSL package (`openssl`) which installs several important cryptographic libraries, enabling OpenSSH to provide encrypted communications.

**9.1. The SSH Protocol**

**9.1.1. Why Use SSH?**

Potential intruders have a variety of tools at their disposal enabling them to disrupt, intercept, and re-route network traffic in an effort to gain access to a system. In general terms, these threats can be categorized as follows:

**Interception of communication between two systems**

The attacker can be somewhere on the network between the communicating parties, copying any information passed between them. He may intercept and keep the information, or alter the information and send it on to the intended recipient.

This attack is usually performed using a *packet sniffer*, a rather common network utility that captures each packet flowing through the network, and analyzes its content.

**Impersonation of a particular host**

Attacker's system is configured to pose as the intended recipient of a transmission. If this strategy works, the user's system remains unaware that it is communicating with the wrong host.

This attack can be performed using a technique known as *DNS poisoning*, or via so-called *IP spoofing*. In the first case, the intruder uses a cracked DNS server to point client systems to a maliciously duplicated host. In the second case, the intruder sends falsified network packets that appear to be from a trusted host.

Both techniques intercept potentially sensitive information and, if the interception is made for hostile reasons, the results can be disastrous. If SSH is used for remote shell login and file copying, these security threats can be greatly diminished. This is because the SSH client and server use digital signatures to verify their identity. Additionally, all communication between the client and server systems is encrypted. Attempts to spoof the identity of either side of a communication does not work, since each packet is encrypted using a key known only by the local and remote systems.

**9.1.2. Main Features**

The SSH protocol provides the following safeguards:
No one can pose as the intended server
   After an initial connection, the client can verify that it is connecting to the same server it had
   connected to previously.

No one can capture the authentication information
   The client transmits its authentication information to the server using strong, 128-bit encryption.

No one can intercept the communication
   All data sent and received during a session is transferred using 128-bit encryption, making
   intercepted transmissions extremely difficult to decrypt and read.

Additionally, it also offers the following options:

It provides secure means to use graphical applications over a network
   Using a technique called X11 forwarding, the client can forward X11 (X Window System)
   applications from the server.

It provides a way to secure otherwise insecure protocols
   The SSH protocol encrypts everything it sends and receives. Using a technique called port
   forwarding, an SSH server can become a conduit to securing otherwise insecure protocols, like
   POP, and increasing overall system and data security.

It can be used to create a secure channel
   The OpenSSH server and client can be configured to create a tunnel similar to a virtual private
   network for traffic between server and client machines.

It supports the Kerberos authentication
   OpenSSH servers and clients can be configured to authenticate using the GSSAPI (Generic
   Security Services Application Program Interface) implementation of the Kerberos network
   authentication protocol.

9.1.3. Protocol Versions
Two varieties of SSH currently exist: version 1, and newer version 2. The OpenSSH suite under
Red Hat Enterprise Linux uses SSH version 2, which has an enhanced key exchange algorithm not
vulnerable to the known exploit in version 1. However, for compatibility reasons, the OpenSSH suite
does support version 1 connections as well.

Important: Avoid Using SSH Version 1
   To ensure maximum security for your connection, it is recommended that only SSH version 2-
   compatible servers and clients are used whenever possible.

9.1.4. Event Sequence of an SSH Connection
The following series of events help protect the integrity of SSH communication between two hosts.

1. A cryptographic handshake is made so that the client can verify that it is communicating with the
   correct server.

2. The transport layer of the connection between the client and remote host is encrypted using a
   symmetric cipher.

3. The client authenticates itself to the server.
4. The remote client interacts with the remote host over the encrypted connection.

9.1.4.1. Transport Layer

The primary role of the transport layer is to facilitate safe and secure communication between the two hosts at the time of authentication and during subsequent communication. The transport layer accomplishes this by handling the encryption and decryption of data, and by providing integrity protection of data packets as they are sent and received. The transport layer also provides compression, speeding the transfer of information.

Once an SSH client contacts a server, key information is exchanged so that the two systems can correctly construct the transport layer. The following steps occur during this exchange:

- Keys are exchanged
- The public key encryption algorithm is determined
- The symmetric encryption algorithm is determined
- The message authentication algorithm is determined
- The hash algorithm is determined

During the key exchange, the server identifies itself to the client with a unique host key. If the client has never communicated with this particular server before, the server's host key is unknown to the client and it does not connect. OpenSSH gets around this problem by accepting the server's host key. This is done after the user is notified and has both accepted and verified the new host key. In subsequent connections, the server's host key is checked against the saved version on the client, providing confidence that the client is indeed communicating with the intended server. If, in the future, the host key no longer matches, the user must remove the client's saved version before a connection can occur.

Caution

It is possible for an attacker to masquerade as an SSH server during the initial contact since the local system does not know the difference between the intended server and a false one set up by an attacker. To help prevent this, verify the integrity of a new SSH server by contacting the server administrator before connecting for the first time or in the event of a host key mismatch.

SSH is designed to work with almost any kind of public key algorithm or encoding format. After an initial key exchange creates a hash value used for exchanges and a shared secret value, the two systems immediately begin calculating new keys and algorithms to protect authentication and future data sent over the connection.

After a certain amount of data has been transmitted using a given key and algorithm (the exact amount depends on the SSH implementation), another key exchange occurs, generating another set of hash values and a new shared secret value. Even if an attacker is able to determine the hash and shared secret value, this information is only useful for a limited period of time.

9.1.4.2. Authentication

Once the transport layer has constructed a secure tunnel to pass information between the two systems, the server tells the client the different authentication methods supported, such as using a private key-encoded signature or typing a password. The client then tries to authenticate itself to the server using one of these supported methods.
SSH servers and clients can be configured to allow different types of authentication, which gives each side the optimal amount of control. The server can decide which encryption methods it supports based on its security model, and the client can choose the order of authentication methods to attempt from the available options.

### 9.1.4.3. Channels

After a successful authentication over the SSH transport layer, multiple channels are opened via a technique called *multiplexing*. Each of these channels handles communication for different terminal sessions and for forwarded X11 sessions.

Both clients and servers can create a new channel. Each channel is then assigned a different number on each end of the connection. When the client attempts to open a new channel, the client sends the channel number along with the request. This information is stored by the server and is used to direct communication to that channel. This is done so that different types of sessions do not affect one another and so that when a given session ends, its channel can be closed without disrupting the primary SSH connection.

Channels also support *flow-control*, which allows them to send and receive data in an orderly fashion. In this way, data is not sent over the channel until the client receives a message that the channel is open.

The client and server negotiate the characteristics of each channel automatically, depending on the type of service the client requests and the way the user is connected to the network. This allows great flexibility in handling different types of remote connections without having to change the basic infrastructure of the protocol.

### 9.2. An OpenSSH Configuration

In order to perform tasks described in this section, you must have superuser privileges. To obtain them, log in as root by typing:

```
~$ su -
Password:
```

#### 9.2.1. Configuration Files

There are two different sets of configuration files: those for client programs (that is, `ssh`, `scp`, and `sftp`), and those for the server (the `sshd` daemon).

System-wide SSH configuration information is stored in the `/etc/ssh/` directory. See Table 9.1, “System-wide configuration files” for a description of its content.

<table>
<thead>
<tr>
<th>Configuration File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/etc/ssh/moduli</code></td>
<td>Contains Diffie-Hellman groups used for the Diffie-Hellman key exchange which is critical for constructing a secure transport layer. When keys are exchanged at the beginning of an SSH session, a shared, secret value is created which cannot be</td>
</tr>
</tbody>
</table>

---

1 A multiplexed connection consists of several signals being sent over a shared, common medium. With SSH, different channels are sent over a common secure connection.
Configuration Files

<table>
<thead>
<tr>
<th>Configuration File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/ssh/ssh_config</td>
<td>The default SSH client configuration file. Note that it is determined by either party alone. This value is then used to provide host authentication.</td>
</tr>
<tr>
<td>/etc/ssh/sshd_config</td>
<td>The configuration file for the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_dsa_key</td>
<td>The DSA private key used by the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_dsa_key.pub</td>
<td>The DSA public key used by the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_key</td>
<td>The RSA private key used by the sshd daemon for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_key.pub</td>
<td>The RSA public key used by the sshd daemon for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_rsa_key</td>
<td>The RSA private key used by the sshd daemon for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_rsa_key.pub</td>
<td>The RSA public key used by the sshd for version 2 of the SSH protocol.</td>
</tr>
</tbody>
</table>

User-specific SSH configuration information is stored in the user's home directory within the ~/.ssh/ directory. See Table 9.2, “User-specific configuration files” for a description of its content.

Table 9.2. User-specific configuration files

<table>
<thead>
<tr>
<th>Configuration File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>~/.ssh/authorized_keys</td>
<td>Holds a list of authorized public keys for servers. When the client connects to a server, the server authenticates the client by checking its signed public key stored within this file.</td>
</tr>
<tr>
<td>~/.ssh/id_dsa</td>
<td>Contains the DSA private key of the user.</td>
</tr>
<tr>
<td>~/.ssh/id_dsa.pub</td>
<td>The DSA public key of the user.</td>
</tr>
<tr>
<td>~/.ssh/id_rsa</td>
<td>The RSA private key used by ssh for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/id_rsa.pub</td>
<td>The RSA public key used by ssh for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/identity</td>
<td>The RSA private key used by ssh for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/identity.pub</td>
<td>The RSA public key used by ssh for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/known_hosts</td>
<td>Contains DSA host keys of SSH servers accessed by the user. This file is very important for ensuring that the SSH client is connecting the correct SSH server.</td>
</tr>
</tbody>
</table>

Refer to the ssh_config and sshd_config man pages for information concerning the various directives available in the SSH configuration files.
9.2.2. Starting an OpenSSH Server

Note: Make Sure You Have Relevant Packages Installed

To run an OpenSSH server, you must have the *openssh-server* and *openssh* packages installed. Refer to Section 1.2.2, "Installing" for more information on how to install new packages in Red Hat Enterprise Linux.

To start the `sshd` daemon, type the following at a shell prompt:

```
~ ]#. service sshd start
```

To stop the running `sshd` daemon, use the following command:

```
~ ]#. service sshd stop
```

If you want the daemon to start automatically at the boot time, type:

```
~ ]#. chkconfig sshd on
```

This will enable the service for all runlevels. For more configuration options, refer to Chapter 7, Controlling Access to Services for the detailed information on how to manage services.

Note that if you reinstall the system, a new set of identification keys will be created. As a result, clients who had connected to the system with any of the OpenSSH tools before the reinstall will see the following message:

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@    WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!     @
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
IT IS POSSIBLE THAT SOMEONE IS DOING SOMETHING NASTY!
Someone could be eavesdropping on you right now (man-in-the-middle attack)!
It is also possible that the RSA host key has just been changed.
```

To prevent this, you can backup the relevant files from the `/etc/ssh/` directory (see Table 9.1, “System-wide configuration files” for a complete list), and restore them whenever you reinstall the system.

9.2.3. Requiring SSH for Remote Connections

For SSH to be truly effective, using insecure connection protocols should be prohibited. Otherwise, a user's password may be protected using SSH for one session, only to be captured later while logging in using Telnet. Some services to disable include `telnet`, `rsh`, `rlogin`, and `vsftpd`.

To disable these services, type the following commands at a shell prompt:

```
~ ]#. chkconfig telnet off
~ ]#. chkconfig rsh off
~ ]#. chkconfig rlogin off
~ ]#. chkconfig vsftpd off
```

For more information on runlevels and configuring services in general, refer to Chapter 7, Controlling Access to Services.
9.2.4. Using a Key-Based Authentication

To improve the system security even further, you can enforce the use of the key-based authentication by disabling the standard password authentication. To do so, open the `/etc/ssh/sshd_config` configuration file in a text editor such as `vi` or `nano`, and change the `PasswordAuthentication` option as follows:

```
PasswordAuthentication no
```

To be able to use `ssh`, `scp`, or `sftp` to connect to the server from a client machine, generate an authorization key pair by following the steps below. Note that keys must be generated for each user separately.

Red Hat Enterprise Linux 6 uses SSH Protocol 2 and RSA keys by default (see Section 9.1.3, "Protocol Versions" for more information).

**Important: Do Not Generate Key Pairs as root**

If you complete the steps as root, only root will be able to use the keys.

**Tip: Backup Your `~/.ssh/` Directory**

If you reinstall your system and want to keep previously generated key pair, backup the `~/.ssh/` directory. After reinstalling, copy it back to your home directory. This process can be done for all users on your system, including root.

9.2.4.1. Generating Key Pairs

To generate an RSA key pair for version 2 of the SSH protocol, follow these steps:

1. Generate an RSA key pair by typing the following at a shell prompt:

   ```bash
   $ ssh-keygen -t rsa
   Generating public/private rsa key pair.
   Enter file in which to save the key (/home/john/.ssh/id_rsa):
   ``

2. Press **Enter** to confirm the default location (that is, `~/.ssh/id_rsa`) for the newly created key.

3. Enter a passphrase, and confirm it by entering it again when prompted to do so. For security reasons, avoid using the same password as you use to log in to your account.

   After this, you will be presented with a message similar to this:

   ```
   Your identification has been saved in /home/john/.ssh/id_rsa.
   Your public key has been saved in /home/john/.ssh/id_rsa.pub.
   The key fingerprint is:
   The key's randomart image is:
   +---[ RSA 2048]----+
   | E. | games
   | . . |     . .
   | o . |
   | . . |
   ```
To generate a DSA key pair for version 2 of the SSH protocol, follow these steps:

1. Generate a DSA key pair by typing the following at a shell prompt:

   ```bash
   $ ssh-keygen -t dsa
   Generating public/private dsa key pair.
   Enter file in which to save the key (/home/john/.ssh/id_dsa):
   Press Enter to confirm the default location (that is, ~/.ssh/id_dsa) for the newly created key.
   
   Enter a passphrase, and confirm it by entering it again when prompted to do so. For security
   reasons, avoid using the same password as you use to log in to your account.
   
   After this, you will be presented with a message similar to this:
   
   Your identification has been saved in /home/john/.ssh/id_dsa.
   Your public key has been saved in /home/john/.ssh/id_dsa.pub.
   The key fingerprint is:
   The key's randomart image is:
   +--[ DSA 1024]----+
   |   .oo"o.       |
   |  ...o Bo       |
   |  .. + o.      |
   |  .  E o       |
   |  o.o  S       |
   |  . o=.        |
   |  . +          |
   |   .           |
   +------------------+
   
   2. Change the permissions of the ~/.ssh/ directory:
   
   ```bash
   $ chmod 775 ~/.ssh
   
   3. Copy the content of ~/.ssh/id_dsa.pub into the ~/.ssh/authorized_keys on the machine
   to which you want to connect, appending it to its end if the file already exists.
6. Change the permissions of the ~/.ssh/authorized_keys file using the following command:

```bash
[-]$ chmod 644 ~/.ssh/authorized_keys
```

To generate an RSA key pair for version 1 of the SSH protocol, follow these steps:

1. Generate an RSA key pair by typing the following at a shell prompt:

```
[-]$ ssh-keygen -t rsa
Generating public/private rsa1 key pair.
Enter file in which to save the key (/home/john/.ssh/identity):
```

2. Press Enter to confirm the default location (that is, ~/.ssh/identity) for the newly created key.

3. Enter a passphrase, and confirm it by entering it again when prompted to do so. For security reasons, avoid using the same password as you use to log into your account.

After this, you will be presented with a message similar to this:

```
Your identification has been saved in /home/john/.ssh/identity.
Your public key has been saved in /home/john/.ssh/identity.pub.
The key fingerprint is:
The key's randomart image is:
+---[RSA1 2048]----+
|                 |
|    o o          |
|     + o E       |
|    . o S        |
|       = +   .   |
|      . = o o...o|
|       .o o  o=o.|
+--------------------+
```

4. Change the permissions of the ~/.ssh/ directory:

```
[-]$ chmod 755 ~/.ssh
```

5. Copy the content of ~/.ssh/identity.pub into the ~/.ssh/authorized_keys on the machine to which you want to connect, appending it to its end if the file already exists.

6. Change the permissions of the ~/.ssh/authorized_keys file using the following command:

```
[-]$ chmod 644 ~/.ssh/authorized_keys
```

Refer to Section 9.2.4.2, “Configuring ssh-agent” for information on how to set up your system to remember the passphrase.
Important: Never Share Your Private Key

The private key is for your personal use only, and it is important that you never give it to anyone.

9.2.4.2. Configuring ssh-agent

To store your passphrase so that you do not have to enter it each time you initiate a connection with a remote machine, you can use the ssh-agent authentication agent. If you are running GNOME, you can configure it to prompt you for your passphrase whenever you log in and remember it during the whole session. Otherwise you can store the passphrase for a certain shell prompt.

To save your passphrase during your GNOME session, follow these steps:

1. Make sure you have the openssh-askpass package installed. If not, refer to Section 1.2.2, “Installing” for more information on how to install new packages in Red Hat Enterprise Linux.

2. Select System → Preferences → Startup Applications from the panel. The Startup Applications Preferences will be started, and the tab containing a list of available startup programs will be shown by default.

![Figure 9.1. Startup Applications Preferences](image-url)
3. Click the **Add** button on the right, and enter `/usr/bin/ssh-add` in the **Command** field.

![Figure 9.2. Adding new application](image)

4. Click **Add** and make sure the check box next to the newly added item is selected.

![Figure 9.3. Enabling the application](image)
5. Log out and then log back in. A dialog box will appear prompting you for your passphrase. From this point on, you should not be prompted for a password by ssh, scp, or sftp.

Figure 9.4. Entering a passphrase

To save your passphrase for a certain shell prompt, use the following command:

```
~]$ ssh-add
Enter passphrase for /home/john/.ssh/id_rsa:
```

Note that when you log out, your passphrase will be forgotten. You must execute the command each time you log in to a virtual console or a terminal window.

9.3. OpenSSH Clients

Note: Make Sure You Have Relevant Packages Installed

To connect to an OpenSSH server from a client machine, you must have the openssh-clients and openssh packages installed. Refer to Section 1.2.2, "Installing" for more information on how to install new packages in Red Hat Enterprise Linux.

9.3.1. Using the ssh Utility

ssh allows you to log in to a remote machine and execute commands there. It is a secure replacement for the rlogin, rsh, and telnet programs.

Similarly to telnet, to log in to a remote machine named penguin.example.com, type the following command at a shell prompt:

```
~]$ ssh penguin.example.com
```

This will log you in with the same username you are using on a local machine. If you want to specify a different one, use a command in the ssh username@hostname form. For example, to log in as john, type:

```
~]$ ssh john@penguin.example.com
```

The first time you initiate a connection, you will be presented with a message similar to this:
The authenticity of host 'penguin.example.com' can't be established.
Are you sure you want to continue connecting (yes/no)?

Type yes to confirm. You will see a notice that the server has been added to the list of known hosts, and a prompt asking for your password:

Warning: Permanently added 'penguin.example.com' (RSA) to the list of known hosts.
john@penguin.example.com's password:

Important

If the SSH server's host key changes, the client notifies the user that the connection cannot proceed until the server's host key is deleted from the ~/.ssh/known_hosts file. To do so, open the file in a text editor, and remove a line containing the remote machine name at the beginning. Before doing this, however, contact the system administrator of the SSH server to verify the server is not compromised.

After entering the password, you will be provided with a shell prompt for the remote machine.

Alternatively, the ssh program can be used to execute a command on the remote machine without logging in to a shell prompt. The syntax for that is ssh [username@]hostname command. For example, if you want to execute the whoami command on penguin.example.com, type:

~]$ ssh john@penguin.example.com whoami
john@penguin.example.com's password:
john

After you enter the correct password, the username will be displayed, and you will return to your local shell prompt.

9.3.2. Using the scp Utility

scp can be used to transfer files between machines over a secure, encrypted connection. In its design, it is very similar to rcp.

To transfer a local file to a remote system, use a command in the following form:

scp localfile username@hostname:remotefile

For example, if you want to transfer .vim/plugin/taglist.vim to a remote machine named penguin.example.com, type the following at a shell prompt:

~]$ scp .vim/plugin/* john@penguin.example.com:.vim/plugin/
john@penguin.example.com's password:
To transfer a remote file to the local system, use the following syntax:

```
scp username@hostname:remotefile localfile
```

For instance, to download the .vimrc configuration file from the remote machine, type:

```
$ scp john@penguin.example.com:.vimrc .vimrc
```

9.3.3. Using the sftp Utility

The `sftp` utility can be used to open a secure, interactive FTP session. In its design, it is similar to `ftp` except that it uses a secure, encrypted connection.

To connect to a remote system, use a command in the following form:

```
sftp username@hostname
```

For example, to log in to a remote machine named penguin.example.com with john as a username, type:

```
$ sftp john@penguin.example.com
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ls</code> [directory]</td>
<td>List the content of a remote directory. If none is supplied, current working directory is used by default.</td>
</tr>
<tr>
<td><code>cd</code> directory</td>
<td>Change the remote working directory to directory.</td>
</tr>
<tr>
<td><code>mkdir</code> directory</td>
<td>Create a remote directory.</td>
</tr>
<tr>
<td><code>rmdir</code> path</td>
<td>Remove a remote directory.</td>
</tr>
<tr>
<td><code>put</code> localfile [remotefile]</td>
<td>Transfer localfile to a remote machine.</td>
</tr>
<tr>
<td><code>get</code> remotefile [localfile]</td>
<td>Transfer remotefile from a remote machine.</td>
</tr>
</tbody>
</table>

For a complete list of available commands, refer to the `sftp` man page.

9.4. More Than a Secure Shell

A secure command line interface is just the beginning of the many ways SSH can be used. Given the proper amount of bandwidth, X11 sessions can be directed over an SSH channel. Or, by using TCP/
IP forwarding, previously insecure port connections between systems can be mapped to specific SSH channels.

9.4.1. X11 Forwarding

To open an X11 session over an SSH connection, use a command in the following form:

```
ssh -Y username@hostname
```

For example, to log in to a remote machine named penguin.example.com with john as a username, type:

```
~]$ ssh -Y john@penguin.example.com
John@penguin.example.com's password:
```

When an X program is run from the secure shell prompt, the SSH client and server create a new secure channel, and the X program data is sent over that channel to the client machine transparently.

X11 forwarding can be very useful. For example, X11 forwarding can be used to create a secure, interactive session of the Printer Configuration utility. To do this, connect to the server using `ssh` and type:

```
~]$ system-config-printer &
```

The Printer Configuration Tool will appear, allowing the remote user to safely configure printing on the remote system.

9.4.2. Port Forwarding

SSH can secure otherwise insecure TCP/IP protocols via port forwarding. When using this technique, the SSH server becomes an encrypted conduit to the SSH client.

Port forwarding works by mapping a local port on the client to a remote port on the server. SSH can map any port from the server to any port on the client. Port numbers do not need to match for this technique to work.

**Note: Using Reserved Port Numbers**

Setting up port forwarding to listen on ports below 1024 requires root level access.

To create a TCP/IP port forwarding channel which listens for connections on the localhost, use a command in the following form:

```
ssh -L local-port:remote-hostname:remote-port username@hostname
```

For example, to check email on a server called mail.example.com using POP3 through an encrypted connection, use the following command:

```
~]$ ssh -L 1100:mail.example.com:110 mail.example.com
```
Once the port forwarding channel is in place between the client machine and the mail server, direct a POP3 mail client to use port \texttt{1100} on the localhost to check for new email. Any requests sent to port \texttt{1100} on the client system will be directed securely to the \texttt{mail.example.com} server.

If \texttt{mail.example.com} is not running an SSH server, but another machine on the same network is, SSH can still be used to secure part of the connection. However, a slightly different command is necessary:

\begin{verbatim}
\$ ssh -L 1100:mail.example.com:110 other.example.com
\end{verbatim}

In this example, POP3 requests from port \texttt{1100} on the client machine are forwarded through the SSH connection on port \texttt{22} to the SSH server, \texttt{other.example.com}. Then, \texttt{other.example.com} connects to port \texttt{110} on \texttt{mail.example.com} to check for new email. Note that when using this technique, only the connection between the client system and \texttt{other.example.com} SSH server is secure.

Port forwarding can also be used to get information securely through network firewalls. If the firewall is configured to allow SSH traffic via its standard port (that is, port 22) but blocks access to other ports, a connection between two hosts using the blocked ports is still possible by redirecting their communication over an established SSH connection.

\begin{important}
Using port forwarding to forward connections in this manner allows any user on the client system to connect to that service. If the client system becomes compromised, the attacker also has access to forwarded services.

System administrators concerned about port forwarding can disable this functionality on the server by specifying a \texttt{No} parameter for the \texttt{AllowTcpForwarding} line in \texttt{/etc/ssh/sshd_config} and restarting the \texttt{sshd} service.
\end{important}

\section*{9.5. Additional Resources}

The OpenSSH and OpenSSL projects are in constant development, and the most up-to-date information for them is available from their websites. The man pages for OpenSSH and OpenSSL tools are also good sources of detailed information.

\subsection*{9.5.1. Installed Documentation}

\texttt{man ssh}

The manual page for \texttt{ssh} containing the full documentation on its usage.

\texttt{man scp}

The manual page for \texttt{scp} containing the full documentation on its usage.

\texttt{man sftp}

The manual page for \texttt{sftp} containing the full documentation on its usage.

\texttt{man sshd}

The manual page for \texttt{sshd} containing the full documentation on its usage.

\texttt{man ssh-keygen}

The manual page for \texttt{ssh-keygen} containing the full documentation on its usage.
Useful Websites

`man ssh_config`
The manual page with full description of available SSH client configuration options.

`man sshd_config`
The manual page with full description of available SSH daemon configuration options.

### 9.5.2. Useful Websites

**http://www.openssh.com/**
The OpenSSH home page containing further documentation, frequently asked questions, links to the mailing lists, bug reports, and other useful resources.

**http://www.openssl.org/**
The OpenSSL home page containing further documentation, frequently asked questions, links to the mailing lists, and other useful resources.

Another implementation of an SSH server.
The BIND DNS Server

DNS (Domain Name System), also known as a nameserver, is a network system that associates hostnames with their respective IP addresses. For users, this has the advantage that they can refer to machines on the network by names that are usually easier to remember than the numerical network addresses. For system administrators, using the nameserver allows them to change the IP address for a host without ever affecting the name-based queries, or to decide which machines handle these queries.

This chapter covers BIND (Berkeley Internet Name Domain), the DNS server included in Red Hat Enterprise Linux. It focuses on the structure of its configuration files, and describes how to administer it both locally and remotely.

10.1. Introduction to DNS

DNS is usually implemented using one or more centralized servers that are authoritative for certain domains. When a client host requests information from a nameserver, it usually connects to port 53. The nameserver then attempts to resolve the name requested. If it does not have an authoritative answer, or does not already have the answer cached from an earlier query, it queries other nameservers, called root nameservers, to determine which nameservers are authoritative for the name in question, and then queries them to get the requested name.

10.1.1. Nameserver Zones

In a DNS server such as BIND, all information is stored in basic data elements called resource records (RR). The resource record is usually a fully qualified domain name (FQDN) of a host, and is broken down into multiple sections organized into a tree-like hierarchy. This hierarchy consists of a main trunk, primary branches, secondary branches, and so on.

Example 10.1. A simple resource record

```
bob.sales.example.com
```

Each level of the hierarchy is divided by a period (that is, .). In Example 10.1, “A simple resource record”, com defines the top-level domain, example its subdomain, and sales the subdomain of example. In this case, bob identifies a resource record that is part of the sales.example.com domain. With the exception of the part furthest to the left (that is, bob), each of these sections is called a zone and defines a specific namespace.

Zones are defined on authoritative nameservers through the use of zone files, which contain definitions of the resource records in each zone. Zone files are stored on primary nameservers (also called master nameservers), where changes are made to the files, and secondary nameservers (also called slave nameservers), which receive zone definitions from the primary nameservers. Both primary and secondary nameservers are authoritative for the zone and look the same to clients. Depending on the configuration, any nameserver can also serve as a primary or secondary server for multiple zones at the same time.

10.1.2. Nameserver Types

There are two nameserver configuration types:
Chapter 10. The BIND DNS Server

authoritative

Authoritative nameservers answer to resource records that are part of their zones only. This category includes both primary (master) and secondary (slave) nameservers.

recursive

Recursive nameservers offer resolution services, but they are not authoritative for any zone. Answers for all resolutions are cached in a memory for a fixed period of time, which is specified by the retrieved resource record.

Although a nameserver can be both authoritative and recursive at the same time, it is recommended not to combine the configuration types. To be able to perform their work, authoritative servers should be available to all clients all the time. On the other hand, since the recursive lookup takes far more time than authoritative responses, recursive servers should be available to a restricted number of clients only, otherwise they are prone to distributed denial of service (DDoS) attacks.

10.1.3. BIND as a Nameserver

BIND consists of a set of DNS-related programs. It contains a monolithic nameserver called named, an administration utility called rndc, and a debugging tool called dig. Refer to Chapter 7, Controlling Access to Services for more information on how to run a service in Red Hat Enterprise Linux.

10.2. Configuring the named Service

When the named service is started, it reads the configuration from the files as described in Table 10.1, "The named service configuration files".

Table 10.1. The named service configuration files

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/named.conf</td>
<td>The main configuration file.</td>
</tr>
<tr>
<td>/etc/named/</td>
<td>An auxiliary directory for configuration files that are included in the main configuration file.</td>
</tr>
</tbody>
</table>

The configuration file consists of a collection of statements with nested options surrounded by opening and closing curly brackets (that is, { and }). Note that when editing the file, you have to be careful not to make any syntax error, otherwise the named service will not start. A typical /etc/named.conf file is organized as follows:

```
statement-1 ["statement-1-name"] [statement-1-class] {
  option-1;
  option-2;
  option-N;
};
statement-2 ["statement-2-name"] [statement-2-class] {
  option-1;
  option-2;
  option-N;
};
statement-N ["statement-N-name"] [statement-N-class] {
  option-1;
  option-2;
  option-N;
};
```
Note: Running BIND in a Chroot Environment

If you have installed the `bind-chroot` package, the BIND service will run in the `/var/named/chroot` environment. In that case, the initialization script will mount the above configuration files using the `mount --bind` command, so that you can manage the configuration outside this environment.

### 10.2.1. Common Statement Types

The following types of statements are commonly used in `/etc/named.conf`:

**acl**

The `acl` (Access Control List) statement allows you to define groups of hosts, so that they can be permitted or denied access to the nameserver. It takes the following form:

```
 acl acl-name {
     match-element;
     ...
   };
```

The `acl-name` statement name is the name of the access control list, and the `match-element` option is usually an individual IP address (such as `10.0.1.1`) or a CIDR network notation (for example, `10.0.1.0/24`). For a list of already defined keywords, see Table 10.2, "Predefined access control lists".

#### Table 10.2. Predefined access control lists

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>Matches every IP address.</td>
</tr>
<tr>
<td>localhost</td>
<td>Matches any IP address that is in use by the local system.</td>
</tr>
<tr>
<td>localnets</td>
<td>Matches any IP address on any network to which the local system is connected.</td>
</tr>
<tr>
<td>none</td>
<td>Does not match any IP address.</td>
</tr>
</tbody>
</table>

The `acl` statement can be especially useful with conjunction with other statements such as `options`. **Example 10.2. “Using acl in conjunction with options”** defines two access control lists, `black-hats` and `red-hats`, and adds `black-hats` on the blacklist while granting `red-hats` a normal access.

#### Example 10.2. Using acl in conjunction with options

```
 acl black-hats {
    10.0.2.0/24;
    192.168.0.0/24;
    1234:5678::9abc/24;
  };
 acl red-hats {
    10.0.1.0/24;
  };
 options {
    blackhole { black-hats; };
    allow-query { red-hats; };
    allow-query-cache { red-hats; };
```
Chapter 10. The BIND DNS Server

include

The **include** statement allows you to include files in the `/etc/named.conf`, so that potentially sensitive data can be placed in a separate file with restricted permissions. It takes the following form:

```plaintext
include "file-name"
```

The *file-name* statement name is an absolute path to a file.

**Example 10.3. Including a file to `/etc/named.conf`**

```plaintext
include "/etc/named.rfc1912.zones"
```

**options**

The **options** statement allows you to define global server configuration options as well as to set defaults for other statements. It can be used to specify the location of the named working directory, the types of queries allowed, and much more. It takes the following form:

```plaintext
options {
  option;
  ...
};
```

For a list of frequently used *option* directives, see *Table 10.3, “Commonly used options”* below.

**Table 10.3. Commonly used options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>allow-query</strong></td>
<td>Specifies which hosts are allowed to query the nameserver for authoritative resource records. It accepts an access control lists, a collection of IP addresses, or networks in the CIDR notation. All hosts are allowed by default.</td>
</tr>
<tr>
<td><strong>allow-query-cache</strong></td>
<td>Specifies which hosts are allowed to query the nameserver for non-authoritative data such as recursive queries. Only <em>localhost</em> and <em>localnets</em> are allowed by default.</td>
</tr>
<tr>
<td><strong>blackhole</strong></td>
<td>Specifies which hosts are not allowed to query the nameserver. This option should be used when particular host or network floods the server with requests. The default option is <em>none</em>.</td>
</tr>
<tr>
<td><strong>directory</strong></td>
<td>Specifies a working directory for the named service. The default option is <code>/var/named/</code>.</td>
</tr>
<tr>
<td><strong>dnssec-enable</strong></td>
<td>Specifies whether to return DNSSEC related resource records. The default option is <em>yes</em>.</td>
</tr>
<tr>
<td><strong>dnssec-validation</strong></td>
<td>Specifies whether to prove that resource records are authentic via DNSSEC. The default option is <em>yes</em>.</td>
</tr>
<tr>
<td><strong>forwarders</strong></td>
<td>Specifies a list of valid IP addresses for nameservers to which the requests should be forwarded for resolution.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>forward</td>
<td>Specifies the behavior of the <code>forwarders</code> directive. It accepts the following options:</td>
</tr>
<tr>
<td></td>
<td>• <strong>first</strong> — The server will query the nameservers listed in the <code>forwarders</code> directive before attempting to resolve the name on its own.</td>
</tr>
<tr>
<td></td>
<td>• <strong>only</strong> — When unable to query the nameservers listed in the <code>forwarders</code> directive, the server will not attempt to resolve the name on its own.</td>
</tr>
<tr>
<td>listen-on</td>
<td>Specifies the IPv4 network interface on which to listen for queries. On a DNS server that also acts as a gateway, you can use this option to answer queries originating from a single network only. All IPv4 interfaces are used by default.</td>
</tr>
<tr>
<td>listen-on-v6</td>
<td>Specifies the IPv6 network interface on which to listen for queries. On a DNS server that also acts as a gateway, you can use this option to answer queries originating from a single network only. All IPv6 interfaces are used by default.</td>
</tr>
<tr>
<td>max-cache-size</td>
<td>Specifies the maximum amount of memory to be used for server caches. When the limit is reached, the server causes records to expire prematurely so that the limit is not exceeded. In a server with multiple views, the limit applies separately to the cache of each view. The default option is <strong>32M</strong>.</td>
</tr>
<tr>
<td>notify</td>
<td>Specifies whether to notify the secondary nameservers when a zone is updated. It accepts the following options:</td>
</tr>
<tr>
<td></td>
<td>• <strong>yes</strong> — The server will notify all secondary nameservers.</td>
</tr>
<tr>
<td></td>
<td>• <strong>no</strong> — The server will <em>not</em> notify any secondary nameserver.</td>
</tr>
<tr>
<td></td>
<td>• <strong>master-only</strong> — The server will notify primary server for the zone only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>explicit</strong> — The server will notify only the secondary servers that are specified in the <code>also-notify</code> list within a zone statement.</td>
</tr>
<tr>
<td>pid-file</td>
<td>Specifies the location of the process ID file created by the named service.</td>
</tr>
<tr>
<td>recursion</td>
<td>Specifies whether to act as a recursive server. The default option is <strong>yes</strong>.</td>
</tr>
<tr>
<td>statistics-file</td>
<td>Specifies an alternate location for statistics files. The <code>/var/named/named.stats</code> file is used by default.</td>
</tr>
</tbody>
</table>

**Important: Restrict Recursive Servers to Selected Clients Only**

To prevent distributed denial of service (DDoS) attacks, it is recommended that you use the `allow-query-cache` option to restrict recursive DNS services for a particular subset of clients only.

Example 10.4. Using the options statement

```plaintext
options {
    allow-query       { localhost; }
    listen-on port    53 { 127.0.0.1; }
    listen-on-v6 port 53 { ::1; }
    max-cache-size    256M;
    directory         "/var/named";
    statistics-file   "/var/named/data/named_stats.txt";
    recursion         yes;
    dnssec-enable     yes;
    dnssec-validation yes;
};
```

zone

The zone statement allows you to define the characteristics of a zone, such as the location of its configuration file and zone-specific options, and can be used to override the global options statements. It takes the following form:

```plaintext
zone zone-name [zone-class] {
    option;
    ...
};
```

The zone-name attribute is the name of the zone, zone-class is the optional class of the zone, and option is a zone statement option as described in Table 10.4, “Commonly used options”.

The zone-name attribute is particularly important, as it is the default value assigned for the $ORIGIN directive used within the corresponding zone file located in the /var/named/ directory. The named daemon appends the name of the zone to any non-fully qualified domain name listed in the zone file. For example, if a zone statement defines the namespace for example.com, use example.com as the zone-name so that it is placed at the end of hostnames within the example.com zone file.

For more information about zone files, refer to Section 10.3, “Editing Zone Files”.

Table 10.4. Commonly used options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow-query</td>
<td>Specifies which clients are allowed to request information about this zone. This option overrides global allow-query option. All query requests are allowed by default.</td>
</tr>
<tr>
<td>allow-transfer</td>
<td>Specifies which secondary servers are allowed to request a transfer of the zone's information. All transfer requests are allowed by default.</td>
</tr>
<tr>
<td>allow-update</td>
<td>Specifies which hosts are allowed to dynamically update information in their zone. The default option is to deny all dynamic update requests. Note that you should be careful when allowing hosts to update information about their zone. Do not set IP addresses in this option unless the server is in the trusted network. Instead, use TSIG key as described in Section 10.6.3, “Transaction SIGnatures (TSIG)”</td>
</tr>
</tbody>
</table>
Common Statement Types

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>Specifies the name of the file in the named working directory that contains the zone’s configuration data.</td>
</tr>
<tr>
<td>masters</td>
<td>Specifies from which IP addresses to request authoritative zone information. This option is used only if the zone is defined as type slave.</td>
</tr>
<tr>
<td>notify</td>
<td>Specifies whether to notify the secondary nameservers when a zone is updated. It accepts the following options:</td>
</tr>
<tr>
<td></td>
<td>• yes — The server will notify all secondary nameservers.</td>
</tr>
<tr>
<td></td>
<td>• no — The server will not notify any secondary nameserver.</td>
</tr>
<tr>
<td></td>
<td>• master-only — The server will notify primary server for the zone only.</td>
</tr>
<tr>
<td></td>
<td>• explicit — The server will notify only the secondary servers that are specified in the also-notify list within a zone statement.</td>
</tr>
<tr>
<td>type</td>
<td>Specifies the zone type. It accepts the following options:</td>
</tr>
<tr>
<td></td>
<td>• delegation-only — Enforces the delegation status of infrastructure zones such as COM, NET, or ORG. Any answer that is received without an explicit or implicit delegation is treated as NXDOMAIN. This option is only applicable in TLDs or root zone files used in recursive or caching implementations.</td>
</tr>
<tr>
<td></td>
<td>• forward — Forwards all requests for information about this zone to other nameservers.</td>
</tr>
<tr>
<td></td>
<td>• hint — A special type of zone used to point to the root nameservers which resolve queries when a zone is not otherwise known. No configuration beyond the default is necessary with a hint zone.</td>
</tr>
<tr>
<td></td>
<td>• master — Designates the nameserver as authoritative for this zone. A zone should be set as the master if the zone’s configuration files reside on the system.</td>
</tr>
<tr>
<td></td>
<td>• slave — Designates the nameserver as a slave server for this zone. Master server is specified in masters directive.</td>
</tr>
</tbody>
</table>

Most changes to the /etc/named.conf file of a primary or secondary nameserver involve adding, modifying, or deleting zone statements, and only a small subset of zone statement options is usually needed for a nameserver to work efficiently.

In Example 10.5, “A zone statement for a primary nameserver”, the zone is identified as example.com, the type is set to master, and the named service is instructed to read the /var/named/example.com.zone file. It also allows only a secondary nameserver (192.168.0.2) to transfer the zone.

Example 10.5. A zone statement for a primary nameserver

```bash
zone "example.com" IN {
    type master;
    file "example.com.zone";
    allow-transfer { 192.168.0.2; }
};
```
A secondary server's zone statement is slightly different. The type is set to slave, and the masters directive is telling named the IP address of the master server.

In Example 10.6, “A zone statement for a secondary nameserver”, the named service is configured to query the primary server at the 192.168.0.1 IP address for information about the example.com zone. The received information is then saved to the /var/named/slaves/example.com.zone file. Note that you have to put all slave zones to /var/named/slaves directory, otherwise the service will fail to transfer the zone.

Example 10.6. A zone statement for a secondary nameserver

```
zone "example.com" {
  type slave;
  file "slaves/example.com.zone";
  masters { 192.168.0.1; };
};
```

### 10.2.2. Other Statement Types

The following types of statements are less commonly used in /etc/named.conf:

**controls**

The controls statement allows you to configure various security requirements necessary to use the rndc command to administer the named service.

Refer to Section 10.4, “Using the rndc Utility” for more information on the rndc utility and its usage.

**key**

The key statement allows you to define a particular key by name. Keys are used to authenticate various actions, such as secure updates or the use of the rndc command. Two options are used with key:

- **algorithm algorithm-name** — The type of algorithm to be used (for example, hmac-md5).
- **secret "key-value"** — The encrypted key.

Refer to Section 10.4, “Using the rndc Utility” for more information on the rndc utility and its usage.

**logging**

The logging statement allows you to use multiple types of logs, so called channels. By using the channel option within the statement, you can construct a customized type of log with its own file name (file), size limit (size), versioning (version), and level of importance (severity). Once a customized channel is defined, a category option is used to categorize the channel and begin logging when the named service is restarted.

By default, named sends standard messages to the rsyslog daemon, which places them in /var/log/messages. Several standard channels are built into BIND with various severity levels, such as default_syslog (which handles informational logging messages) and
**default_debug** (which specifically handles debugging messages). A default category, called **default**, uses the built-in channels to do normal logging without any special configuration.

Customizing the logging process can be a very detailed process and is beyond the scope of this chapter. For information on creating custom BIND logs, refer to the **BIND 9 Administrator Reference Manual** referenced in **Section 10.8.1, “Installed Documentation”**.

**server**

The **server** statement allows you to specify options that affect how the named service should respond to remote nameservers, especially with regard to notifications and zone transfers.

The **transfer-format** option controls the number of resource records that are sent with each message. It can be either **one-answer** (only one resource record), or **many-answers** (multiple resource records). Note that while the **many-answers** option is more efficient, it is not supported by older versions of BIND.

**trusted-keys**

The **trusted-keys** statement allows you to specify assorted public keys used for secure DNS (DNSSEC). Refer to **Section 10.6.4, “DNS Security Extensions (DNSSEC)”** for more information on this topic.

**view**

The **view** statement allows you to create special views depending upon which network the host querying the nameserver is on. This allows some hosts to receive one answer regarding a zone while other hosts receive totally different information. Alternatively, certain zones may only be made available to particular trusted hosts while non-trusted hosts can only make queries for other zones.

Multiple views can be used as long as their names are unique. The **match-clients** option allows you to specify the IP addresses that apply to a particular view. If the **options** statement is used within a view, it overrides the already configured global options. Finally, most **view** statements contain multiple **zone** statements that apply to the **match-clients** list.

Note that the order in which the **view** statements are listed is important, as the first statement that matches a particular client's IP address is used. For more information on this topic, refer to **Section 10.6.1, “Multiple Views”**.

### 10.2.3. Comment Tags

Additionally to statements, the **/etc/named.conf** file can also contain comments. Comments are ignored by the named service, but can prove useful when providing additional information to a user. The following are valid comment tags:

```
//
```

Any text after the **//** characters to the end of the line is considered a comment. For example:

```
notify yes;  // notify all secondary nameservers
```

```
#
```

Any text after the **#** character to the end of the line is considered a comment. For example:
Chapter 10. The BIND DNS Server

notify yes;  # notify all secondary nameservers

/* and */
Any block of text enclosed in /* and */ is considered a comment. For example:

notify yes; /* notify all secondary nameservers */

10.3. Editing Zone Files

As outlined in Section 10.1.1, "Nameserver Zones", zone files contain information about a namespace. They are stored in the named working directory located in /var/named/ by default, and each zone file is named according to the file option in the zone statement, usually in a way that relates to the domain in question and identifies the file as containing zone data, such as example.com.zone.

Table 10.5. The named service zone files

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var/named/</td>
<td>The working directory for the named service. The nameserver is not allowed to write to this directory.</td>
</tr>
<tr>
<td>/var/named/slaves/</td>
<td>The directory for secondary zones. This directory is writable by the named service.</td>
</tr>
<tr>
<td>/var/named/dynamic/</td>
<td>The directory for other files, such as dynamic DNS (DDNS) zones or managed DNSSEC keys. This directory is writable by the named service.</td>
</tr>
<tr>
<td>/var/named/data/</td>
<td>The directory for various statistics and debugging files. This directory is writable by the named service.</td>
</tr>
</tbody>
</table>

A zone file consists of directives and resource records. Directives tell the nameserver to perform tasks or apply special settings to the zone, resource records define the parameters of the zone and assign identities to individual hosts. While the directives are optional, the resource records are required in order to provide name service to a zone.

All directives and resource records should be entered on individual lines.

10.3.1. Common Directives

Directives begin with the dollar sign character (that is, $) followed by the name of the directive, and usually appear at the top of the file. The following directives are commonly used in zone files:

$INCLUDE
The $INCLUDE directive allows you to include another file at the place where it appears, so that other zone settings can be stored in a separate zone file.

Example 10.7. Using the $INCLUDE directive

$INCLUDE /var/named/penguin.example.com
$ORIGIN

The $ORIGIN directive allows you to append the domain name to unqualified records, such as those with the hostname only. Note that the use of this directive is not necessary if the zone is specified in /etc/named.conf, since the zone name is used by default.

In Example 10.8, "Using the $ORIGIN directive", any names used in resource records that do not end in a trailing period (that is, the . character) are appended with example.com.

Example 10.8. Using the $ORIGIN directive

$ORIGIN example.com.

$TTL

The $TTL directive allows you to set the default Time to Live (TTL) value for the zone, that is, how long is a zone record valid. Each resource record can contain its own TTL value, which overrides this directive.

Increasing this value allows remote nameservers to cache the zone information for a longer period of time, reducing the number of queries for the zone and lengthening the amount of time required to proliferate resource record changes.

Example 10.9. Using the $TTL directive

$TTL 1D

10.3.2. Common Resource Records

The following resource records are commonly used in zone files:

A

The Address record specifies an IP address to be assigned to a name. It takes the following form:

hostname IN A IP-address

If the hostname value is omitted, the record will point to the last specified hostname.

In Example 10.10, "Using the A resource record", the requests for server1.example.com are pointed to 10.0.1.3 or 10.0.1.5.

Example 10.10. Using the A resource record

server1 IN A 10.0.1.3
server1 IN A 10.0.1.5

CNAME

The Canonical Name record maps one name to another. Because of this, this type of record is sometimes referred to as an alias record. It takes the following form:
**CNAME** records are most commonly used to point to services that use a common naming scheme, such as `www` for Web servers. However, there are multiple restrictions for their usage:

- CNAME records should not point to other CNAME records. This is mainly to avoid possible infinite loops.
- CNAME records should not contain other resource record types (such as A, NS, MX, etc.). The only exception are DNSSEC related records (that is, RRSIG, NSEC, etc.) when the zone is signed.
- Other resource record that point to the fully qualified domain name (FQDN) of a host (that is, NS, MX, PTR) should not point to a CNAME record.

In *Example 10.11, “Using the CNAME resource record”*, the A record binds a hostname to an IP address, while the CNAME record points the commonly used `www` hostname to it.

**Example 10.11. Using the CNAME resource record**

```
server1 IN A 10.0.1.5
www IN CNAME server1
```

**MX**

The *Mail Exchange* record specifies where the mail sent to a particular namespace controlled by this zone should go. It takes the following form:

```
IN MX preference-value email-server-name
```

The `email-server-name` is a fully qualified domain name (FQDN). The `preference-value` allows numerical ranking of the email servers for a namespace, giving preference to some email systems over others. The MX resource record with the lowest `preference-value` is preferred over the others. However, multiple email servers can possess the same value to distribute email traffic evenly among them.

In *Example 10.12, “Using the MX resource record”*, the first mail.example.com email server is preferred to the mail2.example.com email server when receiving email destined for the example.com domain.

**Example 10.12. Using the MX resource record**

```
example.com. IN MX 10 mail.example.com.
IN MX 20 mail2.example.com.
```

**NS**

The *Nameserver* record announces authoritative nameservers for a particular zone. It takes the following form:

```
IN NS nameserver-name
```
The nameserver-name should be a fully qualified domain name (FQDN). Note that when two nameservers are listed as authoritative for the domain, it is not important whether these nameservers are secondary nameservers, or if one of them is a primary server. They are both still considered authoritative.

Example 10.13. Using the NS resource record

```
IN  NS  dns1.example.com.
IN  NS  dns2.example.com.
```

PTR

The Pointer record points to another part of the namespace. It takes the following form:

```
last-IP-digit IN PTR FQDN-of-system
```

The last-IP-digit directive is the last number in an IP address, and the FQDN-of-system is a fully qualified domain name (FQDN).

PTR records are primarily used for reverse name resolution, as they point IP addresses back to a particular name. Refer to Section 10.3.4.2, “A Reverse Name Resolution Zone File” for more examples of PTR records in use.

SOA

The Start of Authority record announces important authoritative information about a namespace to the nameserver. Located after the directives, it is the first resource record in a zone file. It takes the following form:

```
@  IN  SOA  primary-name-server hostmaster-email ( serial-number 
  time-to-refresh 
  time-to-retry 
  time-to-expire 
  minimum-TTL )
```

The directives are as follows:

- The @ symbol places the SORIGIN directive (or the zone’s name if the SORIGIN directive is not set) as the namespace being defined by this SOA resource record.

- The primary-name-server directive is the hostname of the primary nameserver that is authoritative for this domain.

- The hostmaster-email directive is the email of the person to contact about the namespace.

- The serial-number directive is a numerical value incremented every time the zone file is altered to indicate it is time for the named service to reload the zone.

- The time-to-refresh directive is the numerical value secondary nameservers use to determine how long to wait before asking the primary nameserver if any changes have been made to the zone.

- The time-to-retry directive is a numerical value used by secondary nameservers to determine the length of time to wait before issuing a refresh request in the event that the primary
nameserver is not answering. If the primary server has not replied to a refresh request before the amount of time specified in the `time-to-expire` directive elapses, the secondary servers stop responding as an authority for requests concerning that namespace.

- In BIND 4 and 8, the `minimum-TTL` directive is the amount of time other nameservers cache the zone's information. In BIND 9, it defines how long negative answers are cached for. Caching of negative answers can be set to a maximum of 3 hours (that is, `3H`).

When configuring BIND, all times are specified in seconds. However, it is possible to use abbreviations when specifying units of time other than seconds, such as minutes (M), hours (H), days (D), and weeks (W). Table 10.6, “Seconds compared to other time units” shows an amount of time in seconds and the equivalent time in another format.

<table>
<thead>
<tr>
<th>Seconds</th>
<th>Other Time Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>1M</td>
</tr>
<tr>
<td>1800</td>
<td>30M</td>
</tr>
<tr>
<td>3600</td>
<td>1H</td>
</tr>
<tr>
<td>10800</td>
<td>3H</td>
</tr>
<tr>
<td>21600</td>
<td>6H</td>
</tr>
<tr>
<td>43200</td>
<td>12H</td>
</tr>
<tr>
<td>86400</td>
<td>1D</td>
</tr>
<tr>
<td>259200</td>
<td>3D</td>
</tr>
<tr>
<td>604800</td>
<td>1W</td>
</tr>
<tr>
<td>31536000</td>
<td>365D</td>
</tr>
</tbody>
</table>

Example 10.14. Using the SOA resource record

```
@  IN  SOA  dns1.example.com.  hostmaster.example.com. ( 2001062501 ; serial
21600 ; refresh after 6 hours
3600 ; retry after 1 hour
604800 ; expire after 1 week
86400 ) ; minimum TTL of 1 day
```

10.3.3. Comment Tags
Additionally to resource records and directives, a zone file can also contain comments. Comments are ignored by the named service, but can prove useful when providing additional information to the user. Any text after the semicolon character (that is, ;) to the end of the line is considered a comment. For example:

```
604800 ; expire after 1 week
```

10.3.4. Example Usage
The following examples show the basic usage of zone files.

10.3.4.1. A Simple Zone File

Example 10.15, “A simple zone file” demonstrates the use of standard directives and SOA values.
Example 10.15. A simple zone file

```
@  IN  SOA  dns1.example.com.  hostmaster.example.com. (  
2001062501 ; serial  
21600 ; refresh after 6 hours  
3600 ; retry after 1 hour  
604800 ; expire after 1 week  
86400 ) ; minimum TTL of 1 day  
;  
IN  NS  dns1.example.com.  
IN  NS  dns2.example.com.  
dns1  IN  A  10.0.1.1  
IN  AAAA  aaaa:bbbb::1  
dns2  IN  A  10.0.1.2  
IN  AAAA  aaaa:bbbb::2  
;  
@  IN  MX  10  mail.example.com.  
IN  MX  20  mail2.example.com.  
mail  IN  A  10.0.1.5  
IN  AAAA  aaaa:bbbb::5  
mail2  IN  A  10.0.1.6  
IN  AAAA  aaaa:bbbb::6  
;  
; This sample zone file illustrates sharing the same IP addresses  
; for multiple services:  
;  
services  IN  A  10.0.1.10  
IN  AAAA  aaaa:bbbb::10  
IN  A  10.0.1.11  
IN  AAAA  aaaa:bbbb::11  
ftp  IN  CNAME  services.example.com.  
www  IN  CNAME  services.example.com.  
;  
```

In this example, the authoritative nameservers are set as dns1.example.com and dns2.example.com, and are tied to the 10.0.1.1 and 10.0.1.2 IP addresses respectively using the A record.

The email servers configured with the MX records point to mail and mail2 via A records. Since these names do not end in a trailing period (that is, the . character), the $ORIGIN domain is placed after them, expanding them to mail.example.com and mail2.example.com.

Services available at the standard names, such as www.example.com (WWW), are pointed at the appropriate servers using the CNAME record.

This zone file would be called into service with a zone statement in the /etc/named.conf similar to the following:

```
zeone "example.com" IN {  
type master;  
file "example.com.zone";  
allow-update { none; };  
};  
```
10.3.4.2. A Reverse Name Resolution Zone File

A reverse name resolution zone file is used to translate an IP address in a particular namespace into an fully qualified domain name (FQDN). It looks very similar to a standard zone file, except that the PTR resource records are used to link the IP addresses to a fully qualified domain name as shown in Example 10.16, "A reverse name resolution zone file".

Example 10.16. A reverse name resolution zone file

```plaintext
$ORIGIN 1.0.10.in-addr.arpa.
$TTL 86400
@ IN SOA dns1.example.com. hostmaster.example.com. (2001062501 ; serial
21600 ; refresh after 6 hours
3600 ; retry after 1 hour
604800 ; expire after 1 week
86400 ) ; minimum TTL of 1 day
;
@ IN NS dns1.example.com.
;
1 IN PTR dns1.example.com.
2 IN PTR dns2.example.com.
;
5 IN PTR server1.example.com.
6 IN PTR server2.example.com.
;
3 IN PTR ftp.example.com.
4 IN PTR ftp.example.com.
```

In this example, IP addresses 10.0.1.1 through 10.0.1.6 are pointed to the corresponding fully qualified domain name.

This zone file would be called into service with a zone statement in the `/etc/named.conf` file similar to the following:

```plaintext
zone "1.0.10.in-addr.arpa" IN {
  type master;
  file "example.com.rr.zone";
  allow-update { none; };
};
```

There is very little difference between this example and a standard zone statement, except for the zone name. Note that a reverse name resolution zone requires the first three blocks of the IP address reversed followed by `.in-addr.arpa`. This allows the single block of IP numbers used in the reverse name resolution zone file to be associated with the zone.

10.4. Using the rndc Utility

The `rndc` utility is a command line tool that allows you to administer the named service, both locally and from a remote machine. Its usage is as follows:

```plaintext
rndc [option...] command [command-option]
```
10.4.1. Configuring the Utility

To prevent unauthorized access to the service, named must be configured to listen on the selected port (that is, 953 by default), and an identical key must be used by both the service and the `rndc` utility.

Table 10.7. Relevant files

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/named.conf</td>
<td>The default configuration file for the named service.</td>
</tr>
<tr>
<td>/etc/rndc.conf</td>
<td>The default configuration file for the <code>rndc</code> utility.</td>
</tr>
<tr>
<td>/etc/rndc.key</td>
<td>The default key location.</td>
</tr>
</tbody>
</table>

The `rndc` configuration is located in `/etc/rndc.conf`. If the file does not exist, the utility will use the key located in `/etc/rndc.key`, which was generated automatically during the installation process using the `rndc-confgen -a` command.

The named service is configured using the `controls` statement in the `/etc/named.conf` configuration file as described in Section 10.2.2, “Other Statement Types”. Unless this statement is present, only the connections from the loopback address (that is, 127.0.0.1) will be allowed, and the key located in `/etc/rndc.key` will be used.

For more information on this topic, refer to manual pages and the BIND 9 Administrator Reference Manual listed in Section 10.8, “Additional Resources”.

Important: Set the Correct Permissions

To prevent unprivileged users from sending control commands to the service, make sure only root is allowed to read the `/etc/rndc.key` file:

```
~ ] # chmod o-rwx /etc/rndc.key
```

10.4.2. Checking the Service Status

To check the current status of the named service, use the following command:

```
~ ] # rndc status
version: 9.7.0-P2-RedHat-9.7.0-5.P2.el6
CPUs found: 1
worker threads: 1
number of zones: 16
debug level: 0
xfers running: 0
xfers deferred: 0
soa queries in progress: 0
query logging is OFF
recursive clients: 0/0/1000
tcp clients: 0/100
server is up and running
```

10.4.3. Reloading the Configuration and Zones

To reload both the configuration file and zones, type the following at a shell prompt:

```
~ ] # rndc reload
server reload successful
```
Chapter 10. The BIND DNS Server

This will reload the zones while keeping all previously cached responses, so that you can make changes to the zone files without losing all stored name resolutions.

To reload a single zone, specify its name after the `reload` command, for example:

```
~]# rndc reload localhost
zone reload up-to-date
```

Finally, to reload the configuration file and newly added zones only, type:

```
~]# rndc reconfig
```

**Note: Modifying Zones with Dynamic DNS**

If you intend to manually modify a zone that uses Dynamic DNS (DDNS), make sure you run the `freeze` command first:

```
~]# rndc freeze localhost
```

Once you are finished, run the `thaw` command to allow the DDNS again and reload the zone:

```
~]# rndc thaw localhost
The zone reload and thaw was successful.
```

### 10.4.4. Updating Zone Keys

To update the DNSSEC keys and sign the zone, use the `sign` command. For example:

```
~]# rndc sign localhost
```

Note that to sign a zone with the above command, the `auto-dnssec` option has to be set to `maintain` in the zone statement. For instance:

```
zone "localhost" IN {
  type master;
  file "named.localhost";
  allow-update { none; };
  auto-dnssec maintain;
};
```

### 10.4.5. Enabling the DNSSEC Validation

To enable the DNSSEC validation, type the following at a shell prompt:

```
~]# rndc validation on
```

Similarly, to disable this option, type:

```
~]# rndc validation off
```

Refer to the `options` statement described in Section 10.2.1, "Common Statement Types" for information on how configure this option in `/etc/named.conf`.  

156
10.4.6. Enabling the Query Logging

To enable (or disable in case it is currently enabled) the query logging, run the following command:

```
~# rndc querylog
```

To check the current setting, use the `status` command as described in Section 10.4.2, "Checking the Service Status".

10.5. Using the `dig` Utility

The `dig` utility is a command line tool that allows you to perform DNS lookups and debug a nameserver configuration. Its typical usage is as follows:

```
dig [@server] [option...] name type
```

Refer to Section 10.3.2, "Common Resource Records" for a list of common types.

10.5.1. Looking Up a Nameserver

To look up a nameserver for a particular domain, use the command in the following form:

```
dig name NS
```

In Example 10.17, "A Sample Nameserver Lookup", the `dig` utility is used to display nameservers for example.com.

**Example 10.17. A Sample Nameserver Lookup**

```
~$ dig example.com NS
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 57883
;; flags: qr rd ra; QUERY: 1, ANSWER: 2, AUTHORITY: 0, ADDITIONAL: 0

;; QUESTION SECTION:
;example.com.                   IN      NS

;; ANSWER SECTION:
example.com.            99374   IN      NS      a.iana-servers.net.
example.com.            99374   IN      NS      b.iana-servers.net.

;; Query time: 1 msec
;; SERVER: 10.34.255.7#53(10.34.255.7)
;; WHEN: Wed Aug 18 18:04:06 2010
;; MSG SIZE  rcvd: 77
```

10.5.2. Looking Up an IP Address

To look up an IP address assigned to a particular domain, use the command in the following form:

```
dig name A
```

In Example 10.18, "A Sample IP Address Lookup", the `dig` utility is used to display the IP address of example.com.
Example 10.18. A Sample IP Address Lookup

```bash
$ dig example.com A

;; <<>> DiG 9.7.1-P2-RedHat-9.7.1-2.P2.fc13 <<<> example.com A
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 4849
;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 2, ADDITIONAL: 0

;; QUESTION SECTION:
;example.com.                   IN      A

;; ANSWER SECTION:
example.com.            155606  IN      A       192.0.32.10

;; AUTHORITY SECTION:
example.com.            99175   IN      NS      a.iana-servers.net.
example.com.            99175   IN      NS      b.iana-servers.net.

;; Query time: 1 msec
;; SERVER: 10.34.255.7#53(10.34.255.7)
;; MSG SIZE  rcvd: 93
```

10.5.3. Looking Up a Hostname

To look up a hostname for a particular IP address, use the command in the following form:

```
dig -x address
```

In Example 10.19, “A Sample Hostname Lookup”, the `dig` utility is used to display the hostname assigned to 192.0.32.10.

Example 10.19. A Sample Hostname Lookup

```bash
$ dig -x 192.0.32.10

;; <<>> DiG 9.7.1-P2-RedHat-9.7.1-2.P2.fc13 <<<> -x 192.0.32.10
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 29683
;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 5, ADDITIONAL: 6

;; QUESTION SECTION:
;r32.0.192.in-addr.arpa.      IN      PTR

;; ANSWER SECTION:
10.32.0.192.in-addr.arpa. 21600 IN      PTR     www.example.com.

;; AUTHORITY SECTION:
32.0.192.in-addr.arpa. 21600 IN      NS      b.iana-servers.org.
32.0.192.in-addr.arpa. 21600 IN      NS      c.iana-servers.net.
32.0.192.in-addr.arpa. 21600 IN      NS      d.iana-servers.net.
32.0.192.in-addr.arpa. 21600 IN      NS      ns.icann.org.
32.0.192.in-addr.arpa. 21600 IN      NS      a.iana-servers.net.

;; ADDITIONAL SECTION:
a.iana-servers.net. 13688 IN      A       192.0.34.43
b.iana-servers.org. 5844  IN      A       193.0.0.236
b.iana-servers.org. 5844  IN      AAAA   2001:610:240:2::c100:ec```
10.6. Advanced Features of BIND

Most BIND implementations only use the named service to provide name resolution services or to act as an authority for a particular domain. However, BIND version 9 has a number of advanced features that allow for a more secure and efficient DNS service.

Important: Make Sure the Feature is Supported

Before attempting to use advanced features like DNSSEC, TSIG, or IXFR, make sure that the particular feature is supported by all nameservers in the network environment, especially when you use older versions of BIND or non-BIND servers.

All of the features mentioned are discussed in greater detail in the *BIND 9 Administrator Reference Manual* referenced in Section 10.8.1, “Installed Documentation”.

10.6.1. Multiple Views

Optionally, different information can be presented to a client depending on the network a request originates from. This is primarily used to deny sensitive DNS entries from clients outside of the local network, while allowing queries from clients inside the local network.

To configure multiple views, add the `view` statement to the `/etc/named.conf` configuration file. Use the `match-clients` option to match IP addresses or entire networks and give them special options and zone data.

10.6.2. Incremental Zone Transfers (IXFR)

Incremental Zone Transfers (IXFR) allow a secondary nameserver to only download the updated portions of a zone modified on a primary nameserver. Compared to the standard transfer process, this makes the notification and update process much more efficient.

Note that IXFR is only available when using dynamic updating to make changes to master zone records. If manually editing zone files to make changes, Automatic Zone Transfer (AXFR) is used.

10.6.3. Transaction SIGnatures (TSIG)

Transaction SIGnatures (TSIG) ensure that a shared secret key exists on both primary and secondary nameserver before allowing a transfer. This strengthens the standard IP address-based method of transfer authorization, since attackers would not only need to have access to the IP address to transfer the zone, but they would also need to know the secret key.

Since version 9, BIND also supports TKEY, which is another shared secret key method of authorizing zone transfers.
10.6.4. DNS Security Extensions (DNSSEC)

Domain Name System Security Extensions (DNSSEC) provide origin authentication of DNS data, authenticated denial of existence, and data integrity. When a particular domain is marked as secure, the SERFVAIL response is returned for each resource record that fails the validation.

Note that to debug a DNSSEC-signed domain or a DNSSEC-aware resolver, you can use the `dig` utility as described in Section 10.5, “Using the `dig` Utility”. Useful options are `-dnssec` (requests DNSSEC-related resource records by setting the DNSSEC OK bit), `-cd` (tells recursive nameserver not to validate the response), and `-bufsize=512` (changes the packet size to 512B to get through some firewalls).

10.6.5. Internet Protocol version 6 (IPv6)

Internet Protocol version 6 (IPv6) is supported through the use of AAAA resource records, and the `listen-on-v6` directive as described in Table 10.3, “Commonly used options”.

10.7. Common Mistakes to Avoid

The following is a list of advices how to avoid common mistakes users make when configuring a nameserver:

Use semicolons and curly brackets correctly
- An omitted semicolon or unmatched curly bracket in the `/etc/named.conf` file can prevent the named service from starting.

Use period (that is, the `.` character) correctly
- In zone files, a period at the end of a domain name denotes a fully qualified domain name. If omitted, the named service will append the name of the zone or the value of `$ORIGIN` to complete it.

Increment the serial number when editing a zone file
- If the serial number is not incremented, the primary nameserver will have the correct, new information, but the secondary nameservers will never be notified of the change, and will not attempt to refresh their data of that zone.

Configure the firewall
- If a firewall is blocking connections from the named service to other nameservers, the recommended best practice is to change the firewall settings whenever possible.

**Warning: Avoid Using Fixed UDP Source Ports**

According to the recent research in DNS security, using a fixed UDP source port for DNS queries is a potential security vulnerability that could allow an attacker to conduct cache-poisoning attacks more easily. To prevent this, configure your firewall to allow queries from a random UDP source port.
10.8. Additional Resources
The following sources of information provide additional resources regarding BIND.

10.8.1. Installed Documentation
BIND features a full range of installed documentation covering many different topics, each placed in its own subject directory. For each item below, replace version with the version of the bind package installed on the system:

/usr/share/doc/bind-version/
   The main directory containing the most recent documentation.

/usr/share/doc/bind-version/arm/
   The directory containing the BIND 9 Administrator Reference Manual in HTML and SGML formats, which details BIND resource requirements, how to configure different types of nameservers, how to perform load balancing, and other advanced topics. For most new users of BIND, this is the best place to start.

/usr/share/doc/bind-version/draft/
   The directory containing assorted technical documents that review issues related to the DNS service, and propose some methods to address them.

/usr/share/doc/bind-version/misc/
   The directory designed to address specific advanced issues. Users of BIND version 8 should consult the migration document for specific changes they must make when moving to BIND 9. The options file lists all of the options implemented in BIND 9 that are used in /etc/named.conf.

/usr/share/doc/bind-version/rfc/
   The directory providing every RFC document related to BIND.

There is also a number of man pages for the various applications and configuration files involved with BIND:

man rndc
   The manual page for rndc containing the full documentation on its usage.

man named
   The manual page for named containing the documentation on assorted arguments that can be used to control the BIND nameserver daemon.

man lwresd
   The manual page for lwresd containing the full documentation on the lightweight resolver daemon and its usage.

man named.conf
   The manual page with a comprehensive list of options available within the named configuration file.

man rndc.conf
   The manual page with a comprehensive list of options available within the rndc configuration file.
10.8.2. Useful Websites

http://www.isc.org/software/bind

The home page of the BIND project containing information about current releases as well as a PDF version of the BIND 9 Administrator Reference Manual.

10.8.3. Related Books

DNS and BIND by Paul Albitz and Cricket Liu; O'Reilly & Associates

A popular reference that explains both common and esoteric BIND configuration options, and provides strategies for securing a DNS server.

The Concise Guide to DNS and BIND by Nicolai Langfeldt; Que

Looks at the connection between multiple network services and BIND, with an emphasis on task-oriented, technical topics.
The Apache HTTP Server

HTTP (Hypertext Transfer Protocol) server, or a web server, is a network service that serves content to a client over the web. This typically means web pages, but any other documents can be served as well.

This chapter focuses on the Apache HTTP Server 2.2, a robust, full-featured open source web server developed by the Apache Software Foundation, that is included in Red Hat Enterprise Linux 6. It describes the basic configuration of the httpd service, and covers advanced topics such as adding server modules, setting up virtual hosts, or configuring the secure HTTP server.

11.1. The Apache HTTP Server 2.2

There are important differences between the Apache HTTP Server 2.2 and version 2.0, and if you are upgrading from a previous release of Red Hat Enterprise Linux, you will need to update the httpd service configuration accordingly. This section reviews some of the newly added features, outlines important changes, and guides you through the update of older configuration files.

11.1.1. New Features

The Apache HTTP Server version 2.2 introduces the following enhancements:

• Improved caching modules, that is, mod_cache and mod_disk_cache.

• Support for proxy load balancing, that is, the mod_proxy_balancer module.

• Support for large files on 32-bit architectures, allowing the web server to handle files greater than 2GB.

• A new structure for authentication and authorization support, replacing the authentication modules provided in previous versions.

11.1.2. Notable Changes

Since version 2.0, few changes have been made to the default httpd service configuration:

• The following modules are no longer loaded by default: mod_cern_meta and mod_asis.

• The following module is newly loaded by default: mod_ext_filter.

11.1.3. Updating the Configuration

To update the configuration files from the Apache HTTP Server version 2.0, take the following steps:

1. Make sure all module names are correct, since they may have changed. Adjust the LoadModule directive for each module that has been renamed.

2. Recompile all third party modules before attempting to load them. This typically means authentication and authorization modules.

3. If you use the mod_userdir module, make sure the UserDir directive indicating a directory name (typically public_html) is provided.

1 http://www.apache.org/
4. If you use the Apache HTTP Secure Server, edit the `/etc/httpd/conf.d/ssl.conf` to enable the Secure Sockets Layer (SSL) protocol.

Note that you can check the configuration for possible errors by using the following command:

```
~# service httpd configtest
Syntax OK
```

For more information on upgrading the Apache HTTP Server configuration from version 2.0 to 2.2, refer to [http://httpd.apache.org/docs/2.2/upgrading.html](http://httpd.apache.org/docs/2.2/upgrading.html).

### 11.2. Running the `httpd` Service

This section describes how to start, stop, restart, and check the current status of the Apache HTTP Server. To be able to use the `httpd` service, make sure you have the `httpd` installed. You can do so by using the following command:

```
~# yum install httpd
```

For more information on the concept of runlevels and how to manage system services in Red Hat Enterprise Linux in general, refer to Chapter 7, Controlling Access to Services.

#### 11.2.1. Starting the Service

To run the `httpd` service, type the following at a shell prompt:

```
~# service httpd start
Starting httpd: [ OK ]
```

If you want the service to start automatically at the boot time, use the following command:

```
~# chkconfig httpd on
```

This will enable the service for runlevel 2, 3, 4, and 5. Alternatively, you can use the Service Configuration utility as described in Section 7.2.1.1, "Enabling the Service".

**Note: Using the Secure Server**

If running the Apache HTTP Server as a secure server, a password may be required after the machine boots if using an encrypted private SSL key.

#### 11.2.2. Stopping the Service

To stop the running `httpd` service, type the following at a shell prompt:

```
~# service httpd stop
Stopping httpd: [ OK ]
```

To prevent the service from starting automatically at the boot time, type:

```
~# chkconfig httpd off
```
This will disable the service for all runlevels. Alternatively, you can use the Service Configuration utility as described in Section 7.2.1.2, "Disabling the Service".

11.2.3. Restarting the Service

There are three different ways to restart the running httpd service:

1. To restart the service completely, type:

   ```
   ~
   ]# service httpd restart
   Stopping httpd: [ OK ]
   Starting httpd: [ OK ]
   ```

   This will stop the running httpd service, and then start it again. Use this command after installing or removing a dynamically loaded module such as PHP.

2. To only reload the configuration, type:

   ```
   ~
   ]# service httpd reload
   ```

   This will cause the running httpd service to reload the configuration file. Note that any requests being currently processed will be interrupted, which may cause a client browser to display an error message or render a partial page.

3. To reload the configuration without affecting active requests, type:

   ```
   ~
   ]# service httpd graceful
   ```

   This will cause the running httpd service to reload the configuration file. Note that any requests being currently processed will use the old configuration.

Alternatively, you can use the Service Configuration utility as described in Section 7.2.1.5, "Restarting the Running Service".

11.2.4. Checking the Service Status

To check whether the service is running, type the following at a shell prompt:

```
~
]# service httpd status
httpd (pid 19014) is running...
``` 

Alternatively, you can use the Service Configuration utility as described in Section 7.2.1, “Using the Service Configuration Utility”.

11.3. Editing the Configuration Files

When the httpd service is started, by default, it reads the configuration from locations that are listed in Table 11.1, “The httpd service configuration files”.

Table 11.1. The httpd service configuration files

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/httpd/conf/httpd.conf</td>
<td>The main configuration file.</td>
</tr>
</tbody>
</table>
Chapter 11. The Apache HTTP Server

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/httpd/conf.d/</td>
<td>An auxiliary directory for configuration files that are included in the main configuration file.</td>
</tr>
</tbody>
</table>

Although the default configuration should be suitable for most situations, it is a good idea to become at least familiar with some of the more important configuration options. Note that for any changes to take effect, the web server has to be restarted first. Refer to Section 11.2.3, “Restarting the Service” for more information on how to restart the *httpd* service.

To check the configuration for possible errors, type the following at a shell prompt:

```
~]# service httpd configtest
Syntax OK
```

To make the recovery from mistakes easier, it is recommended that you make a copy of the original file before editing it.

### 11.3.1. Common *httpd* .conf Directives

The following directives are commonly used in the `/etc/httpd/conf/httpd.conf` configuration file:

**<Directory>**

The `<Directory>` directive allows you to apply certain directives to a particular directory only. It takes the following form:

```
<Directory directory>
    directive
    ...
</Directory>
```

The `directory` can be either a full path to an existing directory in the local file system, or a wildcard expression.

This directive can be used to configure additional *cgi-bin* directories for server-side scripts located outside the directory that is specified by `ScriptAlias`. In this case, the `ExecCGI` and `AddHandler` directives must be supplied, and the permissions on the target directory must be set correctly (that is, `0755`).

**Example 11.1. Using the `<Directory>` directive**

```
<Directory /var/www/html>
    Options Indexes FollowSymLinks
    AllowOverride None
    Order allow,deny
    Allow from all
</Directory>
```

**<IfDefine>**

The `IfDefine` directive allows you to use certain directives only when a particular parameter is supplied on the command line. It takes the following form:
The parameter can be supplied at a shell prompt using the `-Dparameter` command line option (for example, `httpd -DEnableHome`). If the optional exclamation mark (that is, `!`) is present, the enclosed directives are used only when the parameter is not specified.

**Example 11.2. Using the `<IfDefine>` directive**

```html
<IfDefine ![parameter> 
  directive 
  ...
</IfDefine>
```

**Example 11.3. Using the `<IfModule>` directive**

```html
<IfModule ![module> 
  directive 
  ...
</IfModule>
```

The module can be identified either by its name, or by the filename. If the optional exclamation mark (that is, `!`) is present, the enclosed directives are used only when the module is not loaded.

**Example 11.3. Using the `<IfModule>` directive**

```html
<IfModule mod_disk_cache.c > 
  CacheEnable disk /
  CacheRoot /var/cache/mod_proxy 
</IfModule>
```

**Example 11.4. Using the `<Location>` directive**

```html
<Location /server-info> 
  SetHandler server-info 
</Location>
```

The `url` can be either a path relative to the directory specified by the `DocumentRoot` directive (for example, `/server-info`), or an external URL such as `http://example.com/server-info`.

**Example 11.4. Using the `<Location>` directive**

```html
<Location /server-info> 
  SetHandler server-info 
</Location>
```
Chapter 11. The Apache HTTP Server

```plaintext
Order deny,allow
Deny from all
Allow from .example.com
</Location>
```

**<Proxy>**

The `<Proxy>` directive allows you to apply certain directives to the proxy server only. It takes the following form:

```plaintext
<Proxy pattern>
  directive...
</Proxy>
```

The `pattern` can be an external URL, or a wildcard expression (for example, `http://example.com/*`).

**Example 11.5. Using the `<Proxy>` directive**

```plaintext
<Proxy *>
  Order deny,allow
  Deny from all
  Allow from .example.com
</Proxy>
```

**<VirtualHost>**

The `<VirtualHost>` directive allows you apply certain directives to particular virtual hosts only. It takes the following form:

```plaintext
<VirtualHost address[:port]...>
  directive...
</VirtualHost>
```

The `address` can be an IP address, a fully qualified domain name, or a special form as described in Table 11.2, “Available `<VirtualHost>` options”.

**Table 11.2. Available `<VirtualHost>` options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Represents all IP addresses.</td>
</tr>
<tr>
<td><em>default</em></td>
<td>Represents unmatched IP addresses.</td>
</tr>
</tbody>
</table>

**Example 11.6. Using the `<VirtualHost>` directive**

```plaintext
<VirtualHost *:80>
  ServerAdmin webmaster@penguin.example.com
  DocumentRoot /www/docs/penguin.example.com
  ServerName penguin.example.com
  ErrorLog logs/penguin.example.com-error_log
  CustomLog logs/penguin.example.com-access_log common
</VirtualHost>
```
Common httpd.conf Directives

AccessFileName
The AccessFileName directive allows you to specify the file to be used to customize access
control information for each directory. It takes the following form:
AccessFileName filename…

The filename is a name of the file to look for in the requested directory. By default, the server
looks for .htaccess.
For security reasons, the directive is typically followed by the Files tag to prevent the files
beginning with .ht from being accessed by web clients. This includes the .htaccess and
.htpasswd files.
Example 11.7. Using the AccessFileName directive
AccessFileName .htaccess
<Files ~ "^\.ht">
Order allow,deny
Deny from all
Satisfy All
</Files>

Action
The Action directive allows you to specify a CGI script to be executed when a certain media type
is requested. It takes the following form:
Action content-type path

The content-type has to be a valid MIME type such as text/html, image/png, or
application/pdf. The path refers to an existing CGI script, and must be relative to the
directory specified by the DocumentRoot directive (for example, /cgi-bin/processimage.cgi).
Example 11.8. Using the Action directive
Action image/png /cgi-bin/process-image.cgi

AddDescription
The AddDescription directive allows you to specify a short description to be displayed in
server-generated directory listings for a given file. It takes the following form:
AddDescription "description" filename…

The description should be a short text enclosed in double quotes (that is, "). The filename
can be a full filename, a file extension, or a wildcard expression.

169


Chapter 11. The Apache HTTP Server

Example 11.9. Using the AddDescription directive

```
AddDescription "GZIP compressed tar archive" .tgz
```

AddEncoding

The AddEncoding directive allows you to specify an encoding type for a particular file extension. It takes the following form:

```
AddEncoding encoding extension...
```

The encoding has to be a valid MIME encoding such as x-compress, x-gzip, etc. The extension is a case sensitive file extension, and is conventionally written with a leading dot (for example, .gz).

This directive is typically used to instruct web browsers to uncompress certain file types as they are downloaded.

Example 11.10. Using the AddEncoding directive

```
AddEncoding x-gzip .gz .tgz
```

AddHandler

The AddHandler directive allows you to map certain file extensions to a selected handler. It takes the following form:

```
AddHandler handler extension...
```

The handler has to be a name of previously defined handler. The extension is a case sensitive file extension, and is conventionally written with a leading dot (for example, .cgi).

This directive is typically used to treat files with the .cgi extension as CGI scripts regardless of the directory they are in. Additionally, it is also commonly used to process server-parsed HTML and image-map files.

Example 11.11. Using the AddHandler option

```
AddHandler cgi-script .cgi
```

AddIcon

The AddIcon directive allows you to specify an icon to be displayed for a particular file in server-generated directory listings. It takes the following form:

```
AddIcon path pattern...
```

The path refers to an existing icon file, and must be relative to the directory specified by the DocumentRoot directive (for example, /icons/folder.png). The pattern can be a filename, a file extension, a wildcard expression, or a special form as described in the following table:
Table 11.3. Available AddIcon options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>^^DIRECTORY^^</td>
<td>Represents a directory.</td>
</tr>
<tr>
<td>^^BLANKICON^^</td>
<td>Represents a blank line.</td>
</tr>
</tbody>
</table>

Example 11.12. Using the AddIcon directive

AddIcon /icons/text.png .txt README

AddIconByEncoding

The AddIconByEncoding directive allows you to specify an icon to be displayed for a particular encoding type in server-generated directory listings. It takes the following form:

AddIconByEncoding path encoding...

The path refers to an existing icon file, and must be relative to the directory specified by the DocumentRoot directive (for example, /icons/compressed.png). The encoding has to be a valid MIME encoding such as x-compress, x-gzip, etc.

Example 11.13. Using the AddIconByEncoding directive

AddIconByEncoding /icons/compressed.png x-compress x-gzip

AddIconByType

The AddIconByType directive allows you to specify an icon to be displayed for a particular media type in server-generated directory listings. It takes the following form:

AddIconByType path content-type...

The path refers to an existing icon file, and must be relative to the directory specified by the DocumentRoot directive (for example, /icons/text.png). The content-type has to be either a valid MIME type (for example, text/html or image/png), or a wildcard expression such as text/*, image/*, etc.

Example 11.14. Using the AddIconByType directive

AddIconByType /icons/video.png video/*

AddLanguage

The AddLanguage directive allows you to associate a file extension with a specific language. It takes the following form:

AddLanguage language extension...

The language has to be a valid MIME language such as cs, en, or fr. The extension is a case sensitive file extension, and is conventionally written with a leading dot (for example, .cs).
This directive is especially useful for web servers that serve content in multiple languages based on the client's language settings.

**Example 11.15. Using the `AddLanguage` directive**

AddLanguage cs .cs .cz

**AddType**

The `AddType` directive allows you to define or override the media type for a particular file extension. It takes the following form:

AddType content-type extension...

The `content-type` has to be a valid MIME type such as `text/html`, `image/png`, etc. The `extension` is a case sensitive file extension, and is conventionally written with a leading dot (for example, `.cs`).

**Example 11.16. Using the `AddType` directive**

AddType application/x-gzip .gz .tgz

**Alias**

The `Alias` directive allows you to refer to files and directories outside the default directory specified by the `DocumentRoot` directive. It takes the following form:

Alias url-path real-path

The `url-path` must be relative to the directory specified by the `DocumentRoot` directive (for example, `/images/`). The `real-path` is a full path to a file or directory in the local file system.

This directive is typically followed by the `Directory` tag with additional permissions to access the target directory. By default, the `/icons/` alias is created so that the icons from `/var/www/icons/` are displayed in server-generated directory listings.

**Example 11.17. Using the `Alias` directive**

Alias /icons/ /var/www/icons/

<Directory "/var/www/icons">
  Options Indexes MultiViews FollowSymLinks
  AllowOverride None
  Order allow,deny
  Allow from all
</Directory>

**Allow**

The `Allow` directive allows you to specify which clients have permission to access a given directory. It takes the following form:
Allow from client...

The client can be a domain name, an IP address (both full and partial), a network/netmask pair, or all for all clients.

Example 11.18. Using the Allow directive

```
Allow from 192.168.1.0/255.255.255.0
```

AllowOverride

The AllowOverride directive allows you to specify which directives in a .htaccess file can override the default configuration. It takes the following form:

```
AllowOverride type...
```

The type has to be one of the available grouping options as described in Table 11.4, “Available AllowOverride options”.

Table 11.4. Available AllowOverride options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>All directives in .htaccess are allowed to override earlier configuration</td>
</tr>
<tr>
<td></td>
<td>settings.</td>
</tr>
<tr>
<td>None</td>
<td>No directive in .htaccess is allowed to override earlier configuration</td>
</tr>
<tr>

<td>Options[=option, ...]</td>
<td>Allows the use of the Options directive. Additionally, you can provide a</td>
</tr>
<tr>
<td></td>
<td>comma-separated list of options to customize which options can be set</td>
</tr>
<tr>
<td></td>
<td>using this directive.</td>
</tr>
</tbody>
</table>

Example 11.19. Using the AllowOverride directive

```
AllowOverride FileInfo AuthConfig Limit
```

BrowserMatch

The BrowserMatch directive allows you to modify the server behavior based on the client's web browser type. It takes the following form:

```
BrowserMatch pattern variable...
```
Chapter 11. The Apache HTTP Server

The pattern is a regular expression to match the User-Agent HTTP header field. The variable is an environment variable that is set when the header field matches the pattern.

By default, this directive is used to deny connections to specific browsers with known issues, and to disable keepalives and HTTP header flushes for browsers that are known to have problems with these actions.

Example 11.20. Using the `BrowserMatch` directive

```bash
BrowserMatch "Mozilla/2" nokeepalive
```

CacheDefaultExpire

The `CacheDefaultExpire` option allows you to set how long to cache a document that does not have any expiration date or the date of its last modification specified. It takes the following form:

```bash
CacheDefaultExpire time
```

The `time` specified in seconds. The default option is 3600 (that is, one hour).

Example 11.21. Using the `CacheDefaultExpire` directive

```bash
CacheDefaultExpire 3600
```

CacheDisable

The `CacheDisable` directive allows you to disable caching of certain URLs. It takes the following form:

```bash
CacheDisable path
```

The `path` must be relative to the directory specified by the `DocumentRoot` directive (for example, `/files/`).

Example 11.22. Using the `CacheDisable` directive

```bash
CacheDisable /temporary
```

CacheEnable

The `CacheEnable` directive allows you to specify a cache type to be used for certain URLs. It takes the following form:

```bash
CacheEnable type url
```

The `type` has to be a valid cache type as described in Table 11.5, “Available cache types”. The `url` can be a path relative to the directory specified by the `DocumentRoot` directive (for example, `/images/`), a protocol (for example, `ftp://`), or an external URL such as `http://example.com/`. 
Table 11.5. Available cache types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mem</td>
<td>The memory-based storage manager.</td>
</tr>
<tr>
<td>disk</td>
<td>The disk-based storage manager.</td>
</tr>
<tr>
<td>fd</td>
<td>The file descriptor cache.</td>
</tr>
</tbody>
</table>

Example 11.23. Using the **CacheEnable** directive

```bash
CacheEnable disk /
```

**CacheLastModifiedFactor**

The **CacheLastModifiedFactor** directive allows you to customize how long to cache a document that does not have any expiration date specified, but that provides information about the date of its last modification. It takes the following form:

```bash
CacheLastModifiedFactor number
```

The *number* is a coefficient to be used to multiply the time that passed since the last modification of the document. The default option is 0.1 (that is, one tenth).

Example 11.24. Using the **CacheLastModifiedFactor** directive

```bash
CacheLastModifiedFactor 0.1
```

**CacheMaxExpire**

The **CacheMaxExpire** directive allows you to specify the maximum amount of time to cache a document. It takes the following form:

```bash
CacheMaxExpire time
```

The *time* is specified in seconds. The default option is 86400 (that is, one day).

Example 11.25. Using the **CacheMaxExpire** directive

```bash
CacheMaxExpire 86400
```

**CacheNegotiatedDocs**

The **CacheNegotiatedDocs** directive allows you to enable caching of the documents that were negotiated on the basis of content. It takes the following form:

```bash
CacheNegotiatedDocs option
```

The *option* has to be a valid keyword as described in Table 11.6, "Available **CacheNegotiatedDocs** options". Since the content-negotiated documents may change over time or because of the input from the requester, the default option is Off.
Table 11.6. Available `CacheNegotiatedDocs` options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>Enables caching the content-negotiated documents.</td>
</tr>
<tr>
<td>Off</td>
<td>Disables caching the content-negotiated documents.</td>
</tr>
</tbody>
</table>

**Example 11.26. Using the `CacheNegotiatedDocs` directive**

```
CacheNegotiatedDocs On
```

**CacheRoot**

The `CacheRoot` directive allows you to specify the directory to store cache files in. It takes the following form:

```
CacheRoot directory
```

The `directory` must be a full path to an existing directory in the local file system. The default option is `/var/cache/mod_proxy/`.

**Example 11.27. Using the `CacheRoot` directive**

```
CacheRoot /var/cache/mod_proxy
```

**CustomLog**

The `CustomLog` directive allows you to specify the log filename and the log file format. It takes the following form:

```
CustomLog path format
```

The `path` refers to a log file, and must be relative to the directory that is specified by the `ServerRoot` directive (that is, `/etc/httpd/` by default). The `format` has to be either an explicit format string, or a format name that was previously defined using the `LogFormat` directive.

**Example 11.28. Using the `CustomLog` directive**

```
CustomLog logs/access_log combined
```

**DefaultIcon**

The `DefaultIcon` directive allows you to specify an icon to be displayed for a file in server-generated directory listings when no other icon is associated with it. It takes the following form:

```
DefaultIcon path
```

The `path` refers to an existing icon file, and must be relative to the directory specified by the `DocumentRoot` directive (for example, `/icons/unknown.png`).
Example 11.29. Using the **DefaultIcon** directive

```text
DefaultIcon /icons/unknown.png
```

**DefaultType**

The **DefaultType** directive allows you to specify a media type to be used in case the proper MIME type cannot be determined by the server. It takes the following form:

```text
DefaultType content-type
```

The *content-type* has to be a valid MIME type such as *text/html*, *image/png*, *application/pdf*, etc.

Example 11.30. Using the **DefaultType** directive

```text
DefaultType text/plain
```

**Deny**

The **Deny** directive allows you to specify which clients are denied access to a given directory. It takes the following form:

```text
Deny from client...
```

The *client* can be a domain name, an IP address (both full and partial), a *network/netmask* pair, or *all* for all clients.

Example 11.31. Using the **Deny** directive

```text
Deny from 192.168.1.1
```

**DirectoryIndex**

The **DirectoryIndex** directive allows you to specify a document to be served to a client when a directory is requested (that is, when the URL ends with the `/` character). It takes the following form:

```text
DirectoryIndex filename...
```

The *filename* is a name of the file to look for in the requested directory. By default, the server looks for *index.html*, and *index.html.var*.

Example 11.32. Using the **DirectoryIndex** directive

```text
DirectoryIndex index.html index.html.var
```
**DocumentRoot**

The **DocumentRoot** directive allows you to specify the main directory from which the content is served. It takes the following form:

```
DocumentRoot directory
```

The `directory` must be a full path to an existing directory in the local file system. The default option is `/var/www/html/`.

**Example 11.33. Using the DocumentRoot directive**

```
DocumentRoot /var/www/html
```

**ErrorDocument**

The **ErrorDocument** directive allows you to specify a document or a message to be displayed as a response to a particular error. It takes the following form:

```
ErrorDocument error-code action
```

The `error-code` has to be a valid code such as 403 (Forbidden), 404 (Not Found), or 500 (Internal Server Error). The `action` can be either a URL (both local and external), or a message string enclosed in double quotes (that is, "").

**Example 11.34. Using the ErrorDocument directive**

```
ErrorDocument 403 "Access Denied"
ErrorDocument 404 /404-not_found.html
```

**ErrorLog**

The **ErrorLog** directive allows you to specify a file to which the server errors are logged. It takes the following form:

```
ErrorLog path
```

The `path` refers to a log file, and can be either absolute, or relative to the directory that is specified by the `ServerRoot` directive (that is, `/etc/httpd/` by default). The default option is `logs/error_log`

**Example 11.35. Using the ErrorLog directive**

```
ErrorLog logs/error_log
```

**ExtendedStatus**

The **ExtendedStatus** directive allows you to enable detailed server status information. It takes the following form:
ExtendedStatus option

The *option* has to be a valid keyword as described in Table 11.7, "Available ExtendedStatus options". The default option is *Off*.

Table 11.7. Available ExtendedStatus options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>Enables generating the detailed server status.</td>
</tr>
<tr>
<td>Off</td>
<td>Disables generating the detailed server status.</td>
</tr>
</tbody>
</table>

Example 11.36. Using the ExtendedStatus directive

ExtendedStatus On

Group

The *Group* directive allows you to specify the group under which the *httpd* service will run. It takes the following form:

Group *group*

The *group* has to be an existing UNIX group. The default option is *apache*.

Note that *Group* is no longer supported inside `<VirtualHost>`, and has been replaced by the *SuexecUserGroup* directive.

Example 11.37. Using the Group directive

Group apache

HeaderName

The *HeaderName* directive allows you to specify a file to be prepended to the beginning of the server-generated directory listing. It takes the following form:

HeaderName *filename*

The *filename* is a name of the file to look for in the requested directory. By default, the server looks for *HEADER.html*.

Example 11.38. Using the HeaderName directive

HeaderName HEADER.html

HostnameLookups

The *HostnameLookups* directive allows you to enable automatic resolving of IP addresses. It takes the following form:
Chapter 11. The Apache HTTP Server

HostnameLookups option

The **option** has to be a valid keyword as described in Table 11.8, "Available HostnameLookups options". To conserve resources on the server, the default option is **Off**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>On</strong></td>
<td>Enables resolving the IP address for each connection so that the hostname can be logged. However, this also adds a significant processing overhead.</td>
</tr>
<tr>
<td><strong>Double</strong></td>
<td>Enables performing the double-reverse DNS lookup. In comparison to the above option, this adds even more processing overhead.</td>
</tr>
<tr>
<td><strong>Off</strong></td>
<td>Disables resolving the IP address for each connection.</td>
</tr>
</tbody>
</table>

Table 11.8. Available HostnameLookups options

Note that when the presence of hostnames is required in server log files, it is often possible to use one of the many log analyzer tools that perform the DNS lookups more efficiently.

Example 11.39. Using the HostnameLookups directive

```
HostnameLookups Off
```

Include

The **Include** directive allows you to include other configuration files. It takes the following form:

```
Include filename
```

The **filename** can be an absolute path, a path relative to the directory specified by the **ServerRoot** directive, or a wildcard expression. All configuration files from the `/etc/httpd/conf.d/` directory are loaded by default.

Example 11.40. Using the Include directive

```
Include conf.d/*.conf
```

IndexIgnore

The **IndexIgnore** directive allows you to specify a list of filenames to be omitted from the server-generated directory listings. It takes the following form:

```
IndexIgnore filename...
```

The **filename** option can be either a full filename, or a wildcard expression.

Example 11.41. Using the IndexIgnore directive

```
IndexIgnore .??* ~ *# HEADER* README* RCS CVS *,v *,t
```
The `IndexOptions` directive allows you to customize the behavior of server-generated directory listings. It takes the following form:

```
IndexOptions option...
```

The `option` has to be a valid keyword as described in Table 11.9, "Available directory listing options". The default options are `Charset=UTF-8`, `FancyIndexing`, `HTMLTable`, `NameWidth=*`, and `VersionSort`.

### Table 11.9. Available directory listing options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Charset=encoding</code></td>
<td>Specifies the character set of a generated web page. The <code>encoding</code> has to be a valid character set such as <code>UTF-8</code> or <code>ISO-8859-2</code>.</td>
</tr>
<tr>
<td><code>Type=content-type</code></td>
<td>Specifies the media type of a generated web page. The <code>content-type</code> has to be a valid MIME type such as <code>text/html</code> or <code>text/plain</code>.</td>
</tr>
<tr>
<td><code>DescriptionWidth=value</code></td>
<td>Specifies the width of the description column. The <code>value</code> can be either a number of characters, or an asterisk (that is, <code>*</code>) to adjust the width automatically.</td>
</tr>
<tr>
<td><code>FancyIndexing</code></td>
<td>Enables advanced features such as different icons for certain files or possibility to re-sort a directory listing by clicking on a column header.</td>
</tr>
<tr>
<td><code>FolderFirst</code></td>
<td>Enables listing directories first, always placing them above files.</td>
</tr>
<tr>
<td><code>HTMLTable</code></td>
<td>Enables the use of HTML tables for directory listings.</td>
</tr>
<tr>
<td><code>IconsAreLinks</code></td>
<td>Enables using the icons as links.</td>
</tr>
<tr>
<td><code>IconHeight=value</code></td>
<td>Specifies an icon height. The <code>value</code> is a number of pixels.</td>
</tr>
<tr>
<td><code>IconWidth=value</code></td>
<td>Specifies an icon width. The <code>value</code> is a number of pixels.</td>
</tr>
<tr>
<td><code>IgnoreCase</code></td>
<td>Enables sorting files and directories in a case-sensitive manner.</td>
</tr>
<tr>
<td><code>IgnoreClient</code></td>
<td>Disables accepting query variables from a client.</td>
</tr>
<tr>
<td><code>NameWidth=value</code></td>
<td>Specifies the width of the filename column. The <code>value</code> can be either a number of characters, or an asterisk (that is, <code>*</code>) to adjust the width automatically.</td>
</tr>
<tr>
<td><code>ScanHTMLTitles</code></td>
<td>Enables parsing the file for a description (that is, the <code>title</code> element) in case it is not provided by the <code>AddDescription</code> directive.</td>
</tr>
<tr>
<td><code>ShowForbidden</code></td>
<td>Enables listing the files with otherwise restricted access.</td>
</tr>
<tr>
<td><code>SuppressColumnSorting</code></td>
<td>Disables re-sorting a directory listing by clicking on a column header.</td>
</tr>
<tr>
<td><code>SuppressDescription</code></td>
<td>Disables reserving a space for file descriptions.</td>
</tr>
<tr>
<td><code>SuppressHTMLPreamble</code></td>
<td>Disables the use of standard HTML preamble when a file specified by the <code>HeaderName</code> directive is present.</td>
</tr>
<tr>
<td><code>SuppressIcon</code></td>
<td>Disables the use of icons in directory listings.</td>
</tr>
<tr>
<td><code>SuppressLastModified</code></td>
<td>Disables displaying the date of the last modification field in directory listings.</td>
</tr>
</tbody>
</table>
Chapter 11. The Apache HTTP Server

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SuppressRules</td>
<td>Disables the use of horizontal lines in directory listings.</td>
</tr>
<tr>
<td>SuppressSize</td>
<td>Disables displaying the file size field in directory listings.</td>
</tr>
<tr>
<td>TrackModified</td>
<td>Enables returning the Last-Modified and ETag values in the HTTP header.</td>
</tr>
<tr>
<td>VersionSort</td>
<td>Enables sorting files that contain a version number in the expected manner.</td>
</tr>
<tr>
<td>XHTML</td>
<td>Enables the use of XHTML 1.0 instead of the default HTML 3.2.</td>
</tr>
</tbody>
</table>

Example 11.42. Using the IndexOptions directive

    IndexOptions FancyIndexing VersionSort NameWidth=* HTMLTable Charset=UTF-8

KeepAlive

The KeepAlive directive allows you to enable persistent connections. It takes the following form:

    KeepAlive option

The option has to be a valid keyword as described in Table 11.10, “Available KeepAlive options”. The default option is off.

Table 11.10. Available KeepAlive options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>Enables the persistent connections. In this case, the server will accept more than one request per connection.</td>
</tr>
<tr>
<td>Off</td>
<td>Disables the keep-alive connections.</td>
</tr>
</tbody>
</table>

Note that when the persistent connections are enabled, on a busy server, the number of child processes can increase rapidly and eventually reach the maximum limit, slowing down the server significantly. To reduce the risk, it is recommended that you set KeepAliveTimeout to a low number, and monitor the /var/log/httpd/logs/error_log log file carefully.

Example 11.43. Using the KeepAlive directive

    KeepAlive off

KeepAliveTimeout

The KeepAliveTimeout directive allows you to specify the amount of time to wait for another request before closing the connection. It takes the following form:

    KeepAliveTimeout time

The time is specified in seconds. The default option is 15.
**LanguagePriority**

The `LanguagePriority` directive allows you to customize the precedence of languages. It takes the following form:

```
LanguagePriority language...
```

The `language` has to be a valid MIME language such as `cs`, `en`, or `fr`.

This directive is especially useful for web servers that serve content in multiple languages based on the client’s language settings.

**Example 11.45. Using the `LanguagePriority` directive**

```
LanguagePriority sk cs en
```

**Listen**

The `Listen` directive allows you to specify IP addresses or ports to listen to. It takes the following form:

```
Listen [ip-address:]port [protocol]
```

The `ip-address` is optional and unless supplied, the server will accept incoming requests on a given `port` from all IP addresses. Since the `protocol` is determined automatically from the port number, it can be usually omitted. The default option is to listen to port 80.

Note that if the server is configured to listen to a port under 1024, only superuser will be able to start the `httpd` service.

**Example 11.46. Using the `Listen` directive**

```
Listen 80
```

**LoadModule**

The `LoadModule` directive allows you to load a Dynamic Shared Object (DSO) module. It takes the following form:

```
LoadModule name path
```

The `name` has to be a valid identifier of the required module. The `path` refers to an existing module file, and must be relative to the directory in which the libraries are placed (that is, `/usr/lib/httpd/` on 32-bit and `/usr/lib64/httpd/` on 64-bit systems by default).
Refer to Section 11.4, “Working with Modules” for more information on the Apache HTTP Server’s DSO support.

Example 11.47. Using the LoadModule directive

```bash
LoadModule php5_module modules/libphp5.so
```

**LogFormat**

The LogFormat directive allows you to specify a log file format. It takes the following form:

```
LogFormat format name
```

The `format` is a string consisting of options as described in Table 11.11, “Common LogFormat options”. The `name` can be used instead of the format string in the CustomLog directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%b</code></td>
<td>Represents the size of the response in bytes.</td>
</tr>
<tr>
<td><code>%h</code></td>
<td>Represents the IP address or hostname of a remote client.</td>
</tr>
<tr>
<td><code>%l</code></td>
<td>Represents the remote log name if supplied. If not, a hyphen (that is, <code>-</code>) is used instead.</td>
</tr>
<tr>
<td><code>%r</code></td>
<td>Represents the first line of the request string as it came from the browser or client.</td>
</tr>
<tr>
<td><code>%s</code></td>
<td>Represents the status code.</td>
</tr>
<tr>
<td><code>%t</code></td>
<td>Represents the date and time of the request.</td>
</tr>
<tr>
<td><code>%u</code></td>
<td>If the authentication is required, it represents the remote user. If not, a hyphen (that is, <code>-</code>) is used instead.</td>
</tr>
<tr>
<td><code>%{field}</code></td>
<td>Represents the content of the HTTP header <code>field</code>. The common options include <code>%{Referer}</code> (the URL of the web page that referred the client to the server) and <code>%{User-Agent}</code> (the type of the web browser making the request).</td>
</tr>
</tbody>
</table>

Example 11.48. Using the LogFormat directive

```
LogFormat "%h %l %u %t "%r" %>s %b" common
```

**LogLevel**

The LogLevel directive allows you to customize the verbosity level of the error log. It takes the following form:

```
LogLevel option
```

The `option` has to be a valid keyword as described in Table 11.12, “Available LogLevel options”. The default option is `warn`. 
### Table 11.12. Available LogLevel options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>emerg</td>
<td>Only the emergency situations when the server cannot perform its work are logged.</td>
</tr>
<tr>
<td>alert</td>
<td>All situations when an immediate action is required are logged.</td>
</tr>
<tr>
<td>crit</td>
<td>All critical conditions are logged.</td>
</tr>
<tr>
<td>error</td>
<td>All error messages are logged.</td>
</tr>
<tr>
<td>warn</td>
<td>All warning messages are logged.</td>
</tr>
<tr>
<td>notice</td>
<td>Even normal, but still significant situations are logged.</td>
</tr>
<tr>
<td>info</td>
<td>Various informational messages are logged.</td>
</tr>
<tr>
<td>debug</td>
<td>Various debugging messages are logged.</td>
</tr>
</tbody>
</table>

#### Example 11.49. Using the LogLevel directive

```bash
LogLevel warn
```

### MaxKeepAliveRequests

The `MaxKeepAliveRequests` directive allows you to specify the maximum number of requests for a persistent connection. It takes the following form:

```bash
MaxKeepAliveRequests number
```

A high `number` can improve the performance of the server. Note that using 0 allows unlimited number of requests. The default option is 100.

#### Example 11.50. Using the MaxKeepAliveRequests option

```bash
MaxKeepAliveRequests 100
```

### NameVirtualHost

The `NameVirtualHost` directive allows you to specify the IP address and port number for a name-based virtual host. It takes the following form:

```bash
NameVirtualHost ip-address[:port]
```

The `ip-address` can be either a full IP address, or an asterisk (that is, *) representing all interfaces. Note that IPv6 addresses have to be enclosed in square brackets (that is, [ and ]). The `port` is optional.

Name-based virtual hosting allows one Apache HTTP Server to serve different domains without using multiple IP addresses.
Important: Using Secure HTTP Connections

Name-based virtual hosts only work with non-secure HTTP connections. If using virtual hosts with a secure server, use IP address-based virtual hosts instead.

Example 11.51. Using the NameVirtualHost directive

NameVirtualHost *:80

Options

The Options directive allows you to specify which server features are available in a particular directory. It takes the following form:

Options option...

The option has to be a valid keyword as described in Table 11.13, "Available server features".

Table 11.13. Available server features

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExecCGI</td>
<td>Enables the execution of CGI scripts.</td>
</tr>
<tr>
<td>FollowSymLinks</td>
<td>Enables following symbolic links in the directory.</td>
</tr>
<tr>
<td>Includes</td>
<td>Enables server-side includes.</td>
</tr>
<tr>
<td>IncludesNOEXEC</td>
<td>Enables server-side includes, but does not allow the execution of commands.</td>
</tr>
<tr>
<td>Indexes</td>
<td>Enables server-generated directory listings.</td>
</tr>
<tr>
<td>MultiViews</td>
<td>Enables content-negotiated &quot;MultiViews&quot;.</td>
</tr>
<tr>
<td>SymLinksIfOwnerMatch</td>
<td>Enables following symbolic links in the directory when both the link and the target file have the same owner.</td>
</tr>
<tr>
<td>All</td>
<td>Enables all of the features above with the exception of MultiViews.</td>
</tr>
<tr>
<td>None</td>
<td>Disables all of the features above.</td>
</tr>
</tbody>
</table>

Example 11.52. Using the Options directive

Options Indexes FollowSymLinks

Order

The Order directive allows you to specify the order in which the Allow and Deny directives are evaluated. It takes the following form:

Order option

The option has to be a valid keyword as described in Table 11.14, "Available Order options". The default option is allow, deny.
Table 11.14. Available Order options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow, deny</td>
<td>Allow directives are evaluated first.</td>
</tr>
<tr>
<td>deny, allow</td>
<td>Deny directives are evaluated first.</td>
</tr>
</tbody>
</table>

Example 11.53. Using the Order directive

```
Order allow,deny
```

**PidFile**

The PidFile directive allows you to specify a file to which the process ID (PID) of the server is stored. It takes the following form:

```
PidFile path
```

The path refers to a pid file, and can be either absolute, or relative to the directory that is specified by the ServerRoot directive (that is, /etc/httpd/ by default). The default option is run/httpd.pid.

Example 11.54. Using the PidFile directive

```
PidFile run/httpd.pid
```

**ProxyRequests**

The ProxyRequests directive allows you to enable forward proxy requests. It takes the following form:

```
ProxyRequests option
```

The option has to be a valid keyword as described in Table 11.15, "Available ProxyRequests options". The default option is Off.

Table 11.15. Available ProxyRequests options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>Enables forward proxy requests.</td>
</tr>
<tr>
<td>Off</td>
<td>Disables forward proxy requests.</td>
</tr>
</tbody>
</table>

Example 11.55. Using the ProxyRequests directive

```
ProxyRequests On
```

**ReadmeName**

The ReadmeName directive allows you to specify a file to be appended to the end of the server-generated directory listing. It takes the following form:
Chapter 11. The Apache HTTP Server

ReadmeName filename

The filename is a name of the file to look for in the requested directory. By default, the server looks for README.html.

Example 11.56. Using the `ReadmeName` directive

```text
ReadmeName README.html
```

Redirect

The `Redirect` directive allows you to redirect a client to another URL. It takes the following form:

```text
Redirect [status] path url
```

The status is optional, and if provided, it has to be a valid keyword as described in Table 11.16, “Available status options”. The path refers to the old location, and must be relative to the directory specified by the `DocumentRoot` directive (for example, /docs). The url refers to the current location of the content (for example, http://docs.example.com).

Table 11.16. Available status options

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>permanent</td>
<td>Indicates that the requested resource has been moved permanently. The 301 (Moved Permanently) status code is returned to a client.</td>
</tr>
<tr>
<td>temp</td>
<td>Indicates that the requested resource has been moved only temporarily. The 302 (Found) status code is returned to a client.</td>
</tr>
<tr>
<td>seeother</td>
<td>Indicates that the requested resource has been replaced. The 303 (See Other) status code is returned to a client.</td>
</tr>
<tr>
<td>gone</td>
<td>Indicates that the requested resource has been removed permanently. The 410 (Gone) status is returned to a client.</td>
</tr>
</tbody>
</table>

Note that for more advanced redirection techniques, you can use the `mod_rewrite` module that is part of the Apache HTTP Server installation.

Example 11.57. Using the `Redirect` directive

```text
Redirect permanent /docs http://docs.example.com
```

ScriptAlias

The `ScriptAlias` directive allows you to specify the location of CGI scripts. It takes the following form:

```text
ScriptAlias url-path real-path
```

The url-path must be relative to the directory specified by the `DocumentRoot` directive (for example, /cgi-bin/). The real-path is a full path to a file or directory in the local file system.
This directive is typically followed by the `Directory` tag with additional permissions to access the target directory. By default, the `/cgi-bin/` alias is created so that the scripts located in the `/var/www/cgi-bin/` are accessible.

The `ScriptAlias` directive is used for security reasons to prevent CGI scripts from being viewed as ordinary text documents.

**Example 11.58. Using the `ScriptAlias` directive**

```apache
ScriptAlias /cgi-bin/ /var/www/cgi-bin/
<Directory "/var/www/cgi-bin">
  AllowOverride None
  Options None
  Order allow,deny
  Allow from all
</Directory>
```

**ServerAdmin**

The `ServerAdmin` directive allows you to specify the email address of the server administrator to be displayed in server-generated web pages. It takes the following form:

```apache
ServerAdmin email
```

The default option is `root@localhost`.

This directive is commonly set to `webmaster@hostname`, where `hostname` is the address of the server. Once set, alias `webmaster` to the person responsible for the web server in `/etc/aliases`, and as superuser, run the `newaliases` command.

**Example 11.59. Using the `ServerAdmin` directive**

```apache
ServerAdmin webmaster@penguin.example.com
```

**ServerName**

The `ServerName` directive allows you to specify the hostname and the port number of a web server. It takes the following form:

```apache
ServerName hostname[:port]
```

The `hostname` has to be a fully qualified domain name (FQDN) of the server. The `port` is optional, but when supplied, it has to match the number specified by the `Listen` directive.

When using this directive, make sure that the IP address and server name pair are included in the `/etc/hosts` file.

**Example 11.60. Using the `ServerName` directive**

```apache
ServerName penguin.example.com:80
```
**ServerRoot**

The **ServerRoot** directive allows you to specify the directory in which the server operates. It takes the following form:

```
ServerRoot directory
```

The `directory` must be a full path to an existing directory in the local file system. The default option is `/etc/httpd/`.

**Example 11.61. Using the ServerRoot directive**

```
ServerRoot /etc/httpd
```

**ServerSignature**

The **ServerSignature** directive allows you to enable displaying information about the server on server-generated documents. It takes the following form:

```
ServerSignature option
```

The `option` has to be a valid keyword as described in Table 11.17, “Available ServerSignature options”. The default option is `On`.

**Table 11.17. Available ServerSignature options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>On</strong></td>
<td>Enables appending the server name and version to server-generated pages.</td>
</tr>
<tr>
<td><strong>Off</strong></td>
<td>Disables appending the server name and version to server-generated pages.</td>
</tr>
<tr>
<td><strong>EMail</strong></td>
<td>Enables appending the server name, version, and the email address of the system administrator as specified by the <code>ServerAdmin</code> directive to server-generated pages.</td>
</tr>
</tbody>
</table>

**Example 11.62. Using the ServerSignature directive**

```
ServerSignature On
```

**ServerTokens**

The **ServerTokens** directive allows you to customize what information are included in the Server response header. It takes the following form:

```
ServerTokens option
```

The `option` has to be a valid keyword as described in Table 11.18, “Available ServerTokens options”. The default option is `OS`. 
Table 11.18. Available ServerTokens options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prod</td>
<td>Includes the product name only (that is, Apache).</td>
</tr>
<tr>
<td>Major</td>
<td>Includes the product name and the major version of the server (for example, 2).</td>
</tr>
<tr>
<td>Minor</td>
<td>Includes the product name and the minor version of the server (for example, 2.2).</td>
</tr>
<tr>
<td>Min</td>
<td>Includes the product name and the minimal version of the server (for example, 2.2.15).</td>
</tr>
<tr>
<td>OS</td>
<td>Includes the product name, the minimal version of the server, and the type of the operating system it is running on (for example, Red Hat).</td>
</tr>
<tr>
<td>Full</td>
<td>Includes all the information above along with the list of loaded modules.</td>
</tr>
</tbody>
</table>

Note that for security reasons, it is recommended to reveal as little information about the server as possible.

Example 11.63. Using the ServerTokens directive

```plaintext
ServerTokens Prod
```

SuexecUserGroup

The SuexecUserGroup directive allows you to specify the user and group under which the CGI scripts will be run. It takes the following form:

```plaintext
SuexecUserGroup user group
```

The user has to be an existing user, and the group must be a valid UNIX group.

For security reasons, the CGI scripts should not be run with root privileges. Note that in <VirtualHost>, SuexecUserGroup replaces the User and Group directives.

Example 11.64. Using the SuexecUserGroup directive

```plaintext
SuexecUserGroup apache apache
```

Timeout

The Timeout directive allows you to specify the amount of time to wait for an event before closing a connection. It takes the following form:

```plaintext
Timeout time
```

The time is specified in seconds. The default option is 60.

Example 11.65. Using the Timeout directive

```plaintext
Timeout 60
```
TypesConfig

The **TypesConfig** allows you to specify the location of the MIME types configuration file. It takes the following form:

```
TypesConfig path
```

The `path` refers to an existing MIME types configuration file, and can be either absolute, or relative to the directory that is specified by the **ServerRoot** directive (that is, `/etc/httpd/` by default). The default option is `/etc/mime.types`.

Note that instead of editing `/etc/mime.types`, the recommended way to add MIME type mapping to the Apache HTTP Server is to use the **AddType** directive.

**Example 11.66. Using the TypesConfig directive**

```
TypesConfig /etc/mime.types
```

UseCanonicalName

The **UseCanonicalName** allows you to specify the way the server refers to itself. It takes the following form:

```
UseCanonicalName option
```

The `option` has to be a valid keyword as described in Table 11.19, "Available UseCanonicalName options". The default option is **Off**.

**Table 11.19. Available UseCanonicalName options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>On</strong></td>
<td>Enables the use of the name that is specified by the <strong>ServerName</strong> directive.</td>
</tr>
<tr>
<td><strong>Off</strong></td>
<td>Disables the use of the name that is specified by the <strong>ServerName</strong> directive. The hostname and port number provided by the requesting client are used instead.</td>
</tr>
<tr>
<td><strong>DNS</strong></td>
<td>Disables the use of the name that is specified by the <strong>ServerName</strong> directive. The hostname determined by a reverse DNS lookup is used instead.</td>
</tr>
</tbody>
</table>

**Example 11.67. Using the UseCanonicalName directive**

```
UseCanonicalName Off
```

User

The **User** directive allows you to specify the user under which the **httpd** service will run. It takes the following form:

```
User user
```
The user has to be an existing UNIX user. The default option is apache.

For security reasons, the httpd service should not be run with root privileges. Note that User is no longer supported inside <VirtualHost>, and has been replaced by the SuexecUserGroup directive.

Example 11.68. Using the User directive
```
User apache
```

UserDir
The UserDir directive allows you to enable serving content from users’ home directories. It takes the following form:

```
UserDir option
```

The option can be either a name of the directory to look for in user’s home directory (typically public_html), or a valid keyword as described in Table 11.20, “Available UserDir options”. The default option is disabled.

Table 11.20. Available UserDir options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled user...</td>
<td>Enables serving content from home directories of given users.</td>
</tr>
<tr>
<td>disabled [user...]</td>
<td>Disables serving content from home directories, either for all users, or, if a space separated list of users is supplied, for given users only.</td>
</tr>
</tbody>
</table>

Note: Set the Correct Permissions

In order for the web server to access the content, the permissions on relevant directories and files must be set correctly. Make sure that all users are able to access the home directories, and that they can access and read the content of the directory specified by the UserDir directive. For example:

```
~]$ chmod a+x /home/username/
~]$ chmod a+rx /home/username/public_html/
```

All files in this directory must be set accordingly.

Example 11.69. Using the UserDir directive
```
UserDir public_html
```

11.3.2. Common ssl.conf Directives

The Secure Sockets Layer (SSL) directives allow you to customize the behavior of the Apache HTTP Secure Server, and in most cases, they are configured appropriately during the installation. Be careful when changing these settings, as incorrect configuration can lead to security vulnerabilities.

The following directive is commonly used in /etc/httpd/conf.d/ssl.conf:
SetEnvIf

The `SetEnvIf` directive allows you to set environment variables based on the headers of incoming connections. It takes the following form:

```
SetEnvIf option pattern [!]variable[=value]...
```

The `option` can be either a HTTP header field, a previously defined environment variable name, or a valid keyword as described in Table 11.21, “Available `SetEnvIf` options”. The `pattern` is a regular expression. The `variable` is an environment variable that is set when the option matches the pattern. If the optional exclamation mark (that is, `!`) is present, the variable is removed instead of being set.

### Table 11.21. Available `SetEnvIf` options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote_Host</td>
<td>Refers to the client's hostname.</td>
</tr>
<tr>
<td>Remote_Addr</td>
<td>Refers to the client's IP address.</td>
</tr>
<tr>
<td>Server_Addr</td>
<td>Refers to the server's IP address.</td>
</tr>
<tr>
<td>Request_Method</td>
<td>Refers to the request method (for example, <code>GET</code>).</td>
</tr>
<tr>
<td>Request_Protocol</td>
<td>Refers to the protocol name and version (for example, <code>HTTP/1.1</code>).</td>
</tr>
<tr>
<td>Request_URI</td>
<td>Refers to the requested resource.</td>
</tr>
</tbody>
</table>

The `SetEnvIf` directive is used to disable HTTP keepalives, and to allow SSL to close the connection without a closing notification from the client browser. This is necessary for certain web browsers that do not reliably shut down the SSL connection.

#### Example 11.70. Using the `SetEnvIf` directive

```
SetEnvIf User-Agent ".*MSIE.*" \
  nokeepalive ssl-unclean-shutdown \
  downgrade-1.0 force-response-1.0
```

Note that for the `/etc/httpd/conf.d/ssl.conf` file to be present, the `mod_ssl` needs to be installed. Refer to Section 11.6, “Setting Up an SSL Server” for more information on how to install and configure an SSL server.

### 11.3.3. Common Multi-Processing Module Directives

The Multi-Processing Module (MPM) directives allow you to customize the behavior of a particular MPM specific server-pool. Since its characteristics differ depending on which MPM is used, the directives are embedded in `IfModule`. By default, the server-pool is defined for both the `prefork` and `worker` MPMS.

The following MPM directives are commonly used in `/etc/httpd/conf/httpd.conf`:

#### MaxClients

The `MaxClients` directive allows you to specify the maximum number of simultaneously connected clients to process at one time. It takes the following form:

```
MaxClients number
```
A high number can improve the performance of the server, although it is not recommended to exceed 256 when using the prefork MPM.

**Example 11.71. Using the **MaxClients** directive**

MaxClients 256

**MaxRequestsPerChild**

The **MaxRequestsPerChild** directive allows you to specify the maximum number of request a child process can serve before it dies. It takes the following form:

MaxRequestsPerChild number

Setting the number to 0 allows unlimited number of requests.

The **MaxRequestsPerChild** directive is used to prevent long-lived processes from causing memory leaks.

**Example 11.72. Using the **MaxRequestsPerChild** directive**

MaxRequestsPerChild 4000

**MaxSpareServers**

The **MaxSpareServers** directive allows you to specify the maximum number of spare child processes. It takes the following form:

MaxSpareServers number

This directive is used by the prefork MPM only.

**Example 11.73. Using the **MaxSpareServers** directive**

MaxSpareServers 20

**MaxSpareThreads**

The **MaxSpareThreads** directive allows you to specify the maximum number of spare server threads. It takes the following form:

MaxSpareThreads number

The number must be greater than or equal to the sum of **MinSpareThreads** and **ThreadsPerChild**. This directive is used by the worker MPM only.

**Example 11.74. Using the **MaxSpareThreads** directive**

MaxSpareThreads 75
MinSpareServers

The MinSpareServers directive allows you to specify the minimum number of spare child processes. It takes the following form:

```
MinSpareServers number
```

Note that a high number can create a heavy processing load on the server. This directive is used by the prefork MPM only.

Example 11.75. Using the MinSpareServers directive

MinSpareServers 5

MinSpareThreads

The MinSpareThreads directive allows you to specify the minimum number of spare server threads. It takes the following form:

```
MinSpareThreads number
```

This directive is used by the worker MPM only.

Example 11.76. Using the MinSpareThreads directive

MinSpareThreads 75

StartServers

The StartServers directive allows you to specify the number of child processes to create when the service is started. It takes the following form:

```
StartServers number
```

Since the child processes are dynamically created and terminated according to the current traffic load, it is usually not necessary to change this value.

Example 11.77. Using the StartServers directive

StartServers 8

ThreadsPerChild

The ThreadsPerChild directive allows you to specify the number of threads a child process can create. It takes the following form:

```
ThreadsPerChild number
```

This directive is used by the worker MPM only.
11.4. Working with Modules

Being a modular application, the httpd service is distributed along with a number of Dynamic Shared Objects (DSOs), which can be dynamically loaded or unloaded at runtime as necessary. By default, these modules are located in /usr/lib/httpd/modules/ on 32-bit and in /usr/lib64/httpd/modules/ on 64-bit systems.

11.4.1. Loading a Module

To load a particular DSO module, use the `LoadModule` directive as described in Section 11.3.1, "Common httpd.conf Directives". Note that modules provided by a separate package often have their own configuration file in the /etc/httpd/conf.d/ directory.

Example 11.79. Loading the mod_ssl DSO

```
LoadModule ssl_module modules/mod_ssl.so
```

Once you are finished, restart the web server to reload the configuration. Refer to Section 11.2.3, "Restarting the Service" for more information on how to restart the httpd service.

11.4.2. Writing a Module

If you intend to create a new DSO module, make sure you have the httpd-devel package installed. To do so, type the following at a shell prompt:

```
~]# yum install httpd-devel
```

This package contains the include files, the header files, and the APache eXtenSion (apxs) utility required to compile a module.

Once written, you can build the module with the following command:

```
~]# apxs -i -a -c module_name.c
```

If the build was successful, you should be able to load the module the same way as any other module that is distributed with the Apache HTTP Server.

11.5. Setting Up Virtual Hosts

The Apache HTTP Server's built in virtual hosting allows the server to provide different information based on which IP address, hostname, or port is being requested.

To create a name-based virtual host, find the virtual host container provided in /etc/httpd/conf/httpd.conf as an example, remove the hash sign (that is, #) from the beginning of each line, and customize the options according to your requirements as shown in Example 11.80, "Sample virtual host configuration".
Example 11.80. Sample virtual host configuration

```
NameVirtualHost penguin.example.com:80
<VirtualHost penguin.example.com:80>
    ServerAdmin webmaster@penguin.example.com
    DocumentRoot /www/docs/penguin.example.com
    ServerName penguin.example.com:80
    ErrorLog logs/penguin.example.com-error_log
    CustomLog logs/penguin.example.com-access_log common
</VirtualHost>
```

Note that `ServerName` must be a valid DNS name assigned to the machine. The `<VirtualHost>` container is highly customizable, and accepts most of the directives available within the main server configuration. Directives that are not supported within this container include `User` and `Group`, which were replaced by `SuexecUserGroup`.

**Note: Changing the Port Number**

If you configure a virtual host to listen on a non-default port, make sure you update the `Listen` directive in the global settings section of the `/etc/httpd/conf/httpd.conf` file accordingly.

To activate a newly created virtual host, the web server has to be restarted first. Refer to Section 11.2.3, “Restarting the Service” for more information on how to restart the `httpd` service.

### 11.6. Setting Up an SSL Server

*Secure Sockets Layer (SSL)* is a cryptographic protocol that allows a server and a client to communicate securely. Along with its extended and improved version called *Transport Layer Security (TLS)*, it ensures both privacy and data integrity. The Apache HTTP Server in combination with `mod_ssl`, a module that uses the OpenSSL toolkit to provide the SSL/TLS support, is commonly referred to as the *SSL server*.

Unlike a regular HTTP connection that can be read and possibly modified by anybody who is able to intercept it, the use of `mod_ssl` prevents any inspection or modification of the transmitted content. This section provides basic information on how to enable this module in the Apache HTTP Server configuration, and guides you through the process of generating private keys and self-signed certificates.

#### 11.6.1. An Overview of Certificates and Security

Secure communication is based on the use of keys. In conventional or *symmetric cryptography*, both ends of the transaction have the same key they can use to decode each other’s transmissions. On the other hand, in public or *asymmetric cryptography*, two keys co-exist: a *private key* that is kept a secret, and a *public key* that is usually shared with the public. While the data encoded with the public key can only be decoded with the private key, data encoded with the private key can in turn only be decoded with the public key.

To provide secure communications using SSL, an SSL server must use a digital certificate signed by a *Certificate Authority* (CA). The certificate lists various attributes of the server (that is, the server hostname, the name of the company, its location, etc.), and the signature produced using the CA’s...
private key. This signature ensures that a particular certificate authority has issued the certificate, and that the certificate has not been modified in any way.

When a web browser establishes a new SSL connection, it checks the certificate provided by the web server. If the certificate does not have a signature from a trusted CA, or if the hostname listed in the certificate does not match the hostname used to establish the connection, it refuses to communicate with the server and usually presents a user with an appropriate error message.

By default, most web browsers are configured to trust a set of widely used certificate authorities. Because of this, an appropriate CA should be chosen when setting up a secure server, so that target users can trust the connection, otherwise they will be presented with an error message, and will have to accept the certificate manually. Since encouraging users to override certificate errors can allow an attacker to intercept the connection, you should use a trusted CA whenever possible. For more information on this, see Table 11.22, “CA lists for most common web browsers”.

Table 11.22. CA lists for most common web browsers

<table>
<thead>
<tr>
<th>Web Browser</th>
<th>Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mozilla Firefox</td>
<td>Mozilla root CA list²</td>
</tr>
<tr>
<td>Opera</td>
<td>The Opera Rootstore³</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>Windows root certificate program members⁴</td>
</tr>
</tbody>
</table>

When setting up an SSL server, you need to generate a certificate request and a private key, and then send the certificate request, proof of the company's identity, and payment to a certificate authority. Once the CA verifies the certificate request and your identity, it will send you a signed certificate you can use with your server. Alternatively, you can create a self-signed certificate that does not contain a CA signature, and thus should be used for testing purposes only.

11.6.2. Enabling the mod_ssl Module

If you intend to set up an SSL server, make sure you have the mod_ssl (the mod_ssl module) and openssl (the OpenSSL toolkit) packages installed. To do so, type the following at a shell prompt:

```bash
~$ yum install mod_ssl openssl
```

This will create the mod_ssl configuration file at `/etc/httpd/conf.d/ssl.conf`, which is included in the main Apache HTTP Server configuration file by default. For the module to be loaded, restart the `httpd` service as described in Section 11.2.3, “Restarting the Service”.

11.6.3. Using an Existing Key and Certificate

If you have a previously created key and certificate, you can configure the SSL server to use these files instead of generating new ones. There are only two situations where this is not possible:

1. You are changing the IP address or domain name.
   
   Certificates are issued for a particular IP address and domain name pair. If one of these values changes, the certificate becomes invalid.

2. You have a certificate from VeriSign, and you are changing the server software.
   
   VeriSign, a widely used certificate authority, issues certificates for a particular software product, IP address, and domain name. Changing the software product renders the certificate invalid.

In either of the above cases, you will need to obtain a new certificate. For more information on this topic, refer to Section 11.6.4, “Generating a New Key and Certificate”.

119
Chapter 11. The Apache HTTP Server

If you wish to use an existing key and certificate, move the relevant files to the `/etc/pki/tls/private/` and `/etc/pki/tls/certs/` directories respectively. You can do so by typing the following commands:

```bash
~]# mv key_file.key /etc/pki/tls/private/hostname.key
~]# mv certificate.crt /etc/pki/tls/certs/hostname.crt
```

Then add the following lines to the `/etc/httpd/conf.d/ssl.conf` configuration file:

```
SSLCertificateFile /etc/pki/tls/certs/hostname.crt
SSLCertificateKeyFile /etc/pki/tls/private/hostname.key
```

To load the updated configuration, restart the `httpd` service as described in Section 11.2.3, “Restarting the Service”.

**Example 11.81. Using a key and certificate from the Red Hat Secure Web Server**

```bash
~]# mv /etc/httpd/conf/httpsd.key /etc/pki/tls/private/penguin.example.com.key
~]# mv /etc/httpd/conf/httpsd.crt /etc/pki/tls/certs/penguin.example.com.crt
```

### 11.6.4. Generating a New Key and Certificate

In order to generate a new key and certificate pair, you must have the `crypto-utils` package installed in your system. You can install it by typing the following at a shell prompt:

```bash
~]# yum install crypto-utils
```

This package provides a set of tools to generate and manage SSL certificates and private keys, and includes `genkey`, the Red Hat Keypair Generation utility that will guide you through the key generation process.

**Important: Replacing an Existing Certificate**

If the server already has a valid certificate and you are replacing it with a new one, specify a different serial number. This ensures that client browsers are notified of this change, update to this new certificate as expected, and do not fail to access the page. To create a new certificate with a custom serial number, use the following command instead of `genkey`:

```bash
~]# openssl req -x509 -new -set_serial number -key hostname.key -out hostname.crt
```

**Note: Remove a Previously Created Key**

If there already is a key file for a particular hostname in your system, `genkey` will refuse to start. In this case, remove the existing file using the following command:

```bash
~]# rm /etc/pki/tls/private/hostname.key
```
To run the utility, use the `genkey` command followed by the appropriate hostname (for example, `penguin.example.com`):

```
~]# genkey hostname
```

To complete the key and certificate creation, take the following steps:

1. Review the target locations in which the key and certificate will be stored.

![Image of the genkey utility](image1)

**Figure 11.1. Running the `genkey` utility**

2. Using the **Tab** key to select the **Next** button, and press **Enter** to proceed to the next screen.

![Image of selecting key size](image2)

**Figure 11.2. Selecting the key size**

Once finished, use the **Tab** key to select the **Next** button, and press **Enter** to initiate the random bits generation process. Depending on the selected key size, this may take some time.
3. Decide whether you wish to send a certificate request to a certificate authority.

Figure 11.3. Generating a certificate request

Use the Tab key to select Yes to compose a certificate request, or No to generate a self-signed certificate. Then press Enter to confirm your choice.

4. Using the Spacebar key, enable (\[*\]) or disable (\[\]) the encryption of the private key.

Figure 11.4. Encrypting the private key

Use the Tab key to select the Next button, and press Enter to proceed to the next screen.
5. If you have enabled the private key encryption, enter an adequate passphrase. Note that for security reasons, it is not displayed as you type, and it must be at least five characters long.

![Figure 11.5. Entering a passphrase](image)

Use the **Tab** key to select the **Next** button, and press **Enter** to proceed to the next screen.

**Important: Do Not Forget the Passphrase**

Entering the correct passphrase is required in order for the server to start. If you lose it, you will need to generate a new key and certificate.

6. Customize the certificate details.

![Figure 11.6. Specifying certificate information](image)

Use the **Tab** key to select the **Next** button, and press **Enter** to finish the key generation.
7. If you have previously enabled the certificate request generation, you will be prompted to send it to a certificate authority.

Figure 11.7. Instructions on how to send a certificate request

Press Enter to return to a shell prompt.

Once generated, add the key and certificate locations to the `/etc/httpd/conf.d/ssl.conf` configuration file:

```
SSLCertificateFile /etc/pki/tls/certs/hostname.crt
SSLCertificateKeyFile /etc/pki/tls/private/hostname.key
```

Finally, restart the `httpd` service as described in Section 11.2.3, "Restarting the Service", so that the updated configuration is loaded.

### 11.7. Additional Resources

To learn more about the Apache HTTP Server, refer to the following resources.

#### 11.7.1. Installed Documentation

`http://localhost/manual/`

The official documentation for the Apache HTTP Server with the full description of its directives and available modules. Note that in order to access this documentation, you must have the `httpd-manual` package installed, and the web server must be running.

`man httpd`

The manual page for the `httpd` service containing the complete list of its command line options.

`man genkey`

The manual page for `genkey` containing the full documentation on its usage.

#### 11.7.2. Useful Websites

`http://httpd.apache.org/`

The official website for the Apache HTTP Server with documentation on all the directives and default modules.
http://www.modssl.org/
   The official website for the mod_ssl module.

http://www.openssl.org/
   The OpenSSL home page containing further documentation, frequently asked questions, links to
   the mailing lists, and other useful resources.
Email

Email was born in the 1960s. The mailbox was a file in a user's home directory that was readable only by that user. Primitive mail applications appended new text messages to the bottom of the file, making the user wade through the constantly growing file to find any particular message. This system was only capable of sending messages to users on the same system.

The first network transfer of an electronic mail message file took place in 1971 when a computer engineer named Ray Tomlinson sent a test message between two machines via ARPANET—the precursor to the Internet. Communication via email soon became very popular, comprising 75 percent of ARPANET's traffic in less than two years.

Today, email systems based on standardized network protocols have evolved into some of the most widely used services on the Internet. Red Hat Enterprise Linux offers many advanced applications to serve and access email.

This chapter reviews modern email protocols in use today, and some of the programs designed to send and receive email.

12.1. Email Protocols

Today, email is delivered using a client/server architecture. An email message is created using a mail client program. This program then sends the message to a server. The server then forwards the message to the recipient's email server, where the message is then supplied to the recipient's email client.

To enable this process, a variety of standard network protocols allow different machines, often running different operating systems and using different email programs, to send and receive email.

The following protocols discussed are the most commonly used in the transfer of email.

12.1.1. Mail Transport Protocols

Mail delivery from a client application to the server, and from an originating server to the destination server, is handled by the Simple Mail Transfer Protocol (SMTP).

12.1.1.1. SMTP

The primary purpose of SMTP is to transfer email between mail servers. However, it is critical for email clients as well. To send email, the client sends the message to an outgoing mail server, which in turn contacts the destination mail server for delivery. For this reason, it is necessary to specify an SMTP server when configuring an email client.

Under Red Hat Enterprise Linux, a user can configure an SMTP server on the local machine to handle mail delivery. However, it is also possible to configure remote SMTP servers for outgoing mail.

One important point to make about the SMTP protocol is that it does not require authentication. This allows anyone on the Internet to send email to anyone else or even to large groups of people. It is this characteristic of SMTP that makes junk email or spam possible. Imposing relay restrictions limits random users on the Internet from sending email through your SMTP server, to other servers on the internet. Servers that do not impose such restrictions are called open relay servers.

Red Hat Enterprise Linux provides the Postfix and Sendmail SMTP programs.
Chapter 12. Email

12.1.2. Mail Access Protocols

There are two primary protocols used by email client applications to retrieve email from mail servers: the Post Office Protocol (POP) and the Internet Message Access Protocol (IMAP).

12.1.2.1. POP

The default POP server under Red Hat Enterprise Linux is **Dovecot** and is provided by the **dovecot** package.

**Note: Installing the dovecot package**

In order to use **Dovecot**, first ensure the **dovecot** package is installed on your system by running, as root:

```
~]# yum install dovecot
```

For more information on installing packages with Yum, refer to **Section 1.2.2, “Installing”**.

When using a POP server, email messages are downloaded by email client applications. By default, most POP email clients are automatically configured to delete the message on the email server after it has been successfully transferred, however this setting usually can be changed.

POP is fully compatible with important Internet messaging standards, such as **Multipurpose Internet Mail Extensions (MIME)**, which allow for email attachments.

POP works best for users who have one system on which to read email. It also works well for users who do not have a persistent connection to the Internet or the network containing the mail server. Unfortunately for those with slow network connections, POP requires client programs upon authentication to download the entire content of each message. This can take a long time if any messages have large attachments.

The most current version of the standard POP protocol is **POP3**.

There are, however, a variety of lesser-used POP protocol variants:

- **APOP** — POP3 with MDS (Monash Directory Service) authentication. An encoded hash of the user’s password is sent from the email client to the server rather then sending an unencrypted password.

- **KPOP** — POP3 with Kerberos authentication.

- **RPOP** — POP3 with RPOP authentication. This uses a per-user ID, similar to a password, to authenticate POP requests. However, this ID is not encrypted, so RPOP is no more secure than standard POP.

For added security, it is possible to use **Secure Socket Layer (SSL)** encryption for client authentication and data transfer sessions. This can be enabled by using the **pop3s** service, or by using the `/usr/sbin/stunnel` application. For more information on securing email communication, refer to **Section 12.5.1, “Securing Communication”**.

12.1.2.2. IMAP

The default IMAP server under Red Hat Enterprise Linux is **Dovecot** and is provided by the **dovecot** package. Refer to **Section 12.1.2.1, “POP”** for information on how to install **Dovecot**.
When using an IMAP mail server, email messages remain on the server where users can read or delete them. IMAP also allows client applications to create, rename, or delete mail directories on the server to organize and store email.

IMAP is particularly useful for users who access their email using multiple machines. The protocol is also convenient for users connecting to the mail server via a slow connection, because only the email header information is downloaded for messages until opened, saving bandwidth. The user also has the ability to delete messages without viewing or downloading them.

For convenience, IMAP client applications are capable of caching copies of messages locally, so the user can browse previously read messages when not directly connected to the IMAP server.

IMAP, like POP, is fully compatible with important Internet messaging standards, such as MIME, which allow for email attachments.

For added security, it is possible to use SSL encryption for client authentication and data transfer sessions. This can be enabled by using the `imaps` service, or by using the `/usr/sbin/stunnel` program. For more information on securing email communication, refer to Section 12.5.1, “Securing Communication”.

Other free, as well as commercial, IMAP clients and servers are available, many of which extend the IMAP protocol and provide additional functionality.

### 12.1.2.3. Dovecot

The `imap-login` and `pop3-login` processes which implement the IMAP and POP3 protocols are spawned by the master `dovecot` daemon included in the `dovecot` package. The use of IMAP and POP is configured through the `/etc/dovecot/dovecot.conf` configuration file; by default `dovecot` runs IMAP and POP3 together with their secure versions using SSL. To configure `dovecot` to use POP, complete the following steps:

1. Edit the `/etc/dovecot/dovecot.conf` configuration file to make sure the `protocols` variable is uncommented (remove the hash sign (`#`) at the beginning of the line) and contains the `pop3` argument. For example:

   ```
   protocols = imap imaps pop3 pop3s
   ```

   When the `protocols` variable is left commented out, `dovecot` will use the default values specified for this variable.

2. Make that change operational for the current session by running the following command:

   ```
   ~]# service dovecot restart
   ```

3. Make that change operational after the next reboot by running the command:

   ```
   ~]# chkconfig dovecot on
   ```

**Note**

Please note that `dovecot` only reports that it started the IMAP server, but also starts the POP3 server.
Unlike SMTP, both IMAP and POP3 require connecting clients to authenticate using a username and password. By default, passwords for both protocols are passed over the network unencrypted.

To configure SSL on dovecot:

- Edit the `/etc/pki/dovecot/dovecot-openssl.conf` configuration file as you prefer. However, in a typical installation, this file does not require modification.

- Rename, move or delete the files `/etc/pki/dovecot/certs/dovecot.pem` and `/etc/pki/dovecot/private/dovecot.pem`.

- Execute the `/usr/libexec/dovecot/mkcert.sh` script which creates the dovecot self signed certificates. These certificates are copied in the `/etc/pki/dovecot/certs` and `/etc/pki/dovecot/private` directories. To implement the changes, restart dovecot:

```
~]# service dovecot restart
```

More details on dovecot can be found online at [http://www.dovecot.org](http://www.dovecot.org).

### 12.2. Email Program Classifications

In general, all email applications fall into at least one of three classifications. Each classification plays a specific role in the process of moving and managing email messages. While most users are only aware of the specific email program they use to receive and send messages, each one is important for ensuring that email arrives at the correct destination.

#### 12.2.1. Mail Transport Agent

A Mail Transport Agent (MTA) transports email messages between hosts using SMTP. A message may involve several MTAs as it moves to its intended destination.

While the delivery of messages between machines may seem rather straightforward, the entire process of deciding if a particular MTA can or should accept a message for delivery is quite complicated. In addition, due to problems from spam, use of a particular MTA is usually restricted by the MTA's configuration or the access configuration for the network on which the MTA resides.

Many modern email client programs can act as an MTA when sending email. However, this action should not be confused with the role of a true MTA. The sole reason email client programs are capable of sending email like an MTA is because the host running the application does not have its own MTA. This is particularly true for email client programs on non-UNIX-based operating systems. However, these client programs only send outbound messages to an MTA they are authorized to use and do not directly deliver the message to the intended recipient's email server.

Since Red Hat Enterprise Linux offers two MTAs—Postfix and Sendmail—email client programs are often not required to act as an MTA. Red Hat Enterprise Linux also includes a special purpose MTA called Fetchmail.

For more information on Postfix, Sendmail, and Fetchmail, refer to Section 12.3, “Mail Transport Agents”.

#### 12.2.2. Mail Delivery Agent

A Mail Delivery Agent (MDA) is invoked by the MTA to file incoming email in the proper user's mailbox. In many cases, the MDA is actually a Local Delivery Agent (LDA), such as mail or Procmail.
Any program that actually handles a message for delivery to the point where it can be read by an email client application can be considered an MDA. For this reason, some MTAs (such as Sendmail and Postfix) can fill the role of an MDA when they append new email messages to a local user’s mail spool file. In general, MDAs do not transport messages between systems nor do they provide a user interface; MDAs distribute and sort messages on the local machine for an email client application to access.

### 12.2.3. Mail User Agent

A Mail User Agent (MUA) is synonymous with an email client application. An MUA is a program that, at the very least, allows a user to read and compose email messages. Many MUAs are capable of retrieving messages via the POP or IMAP protocols, setting up mailboxes to store messages, and sending outbound messages to an MTA.

MUAs may be graphical, such as Evolution, or have simple text-based interfaces, such as pine.

### 12.3. Mail Transport Agents

Red Hat Enterprise Linux offers two primary MTAs: Postfix and Sendmail. Postfix is configured as the default MTA, although it is easy to switch the default MTA to Sendmail. To switch the default MTA to Sendmail, you can either uninstall Postfix or use the following command to switch to Sendmail:

```
~]# alternatives --config mta
```

You can also use the following command to enable/disable the desired service:

```
~]# chkconfig <service> <on/off>
```

### 12.3.1. Postfix

Originally developed at IBM by security expert and programmer Wietse Venema, Postfix is a Sendmail-compatible MTA that is designed to be secure, fast, and easy to configure.

To improve security, Postfix uses a modular design, where small processes with limited privileges are launched by a master daemon. The smaller, less privileged processes perform very specific tasks related to the various stages of mail delivery and run in a change rooted environment to limit the effects of attacks.

Configuring Postfix to accept network connections from hosts other than the local computer takes only a few minor changes in its configuration file. Yet for those with more complex needs, Postfix provides a variety of configuration options, as well as third party add ons that make it a very versatile and full-featured MTA.

The configuration files for Postfix are human readable and support upward of 250 directives. Unlike Sendmail, no macro processing is required for changes to take effect and the majority of the most commonly used options are described in the heavily commented files.

#### 12.3.1.1. The Default Postfix Installation

The Postfix executable is `/usr/sbin/postfix`. This daemon launches all related processes needed to handle mail delivery.

Postfix stores its configuration files in the `/etc/postfix/` directory. The following is a list of the more commonly used files:
Chapter 12. Email

- **access** — Used for access control, this file specifies which hosts are allowed to connect to Postfix.

- **main.cf** — The global Postfix configuration file. The majority of configuration options are specified in this file.

- **master.cf** — Specifies how Postfix interacts with various processes to accomplish mail delivery.

- **transport** — Maps email addresses to relay hosts.

The **aliases** file can be found in the `/etc/` directory. This file is shared between Postfix and Sendmail. It is a configurable list required by the mail protocol that describes user ID aliases.

**Important**

The default `/etc/postfix/main.cf` file does not allow Postfix to accept network connections from a host other than the local computer. For instructions on configuring Postfix as a server for other clients, refer to Section 12.3.1.2, “Basic Postfix Configuration”.

Restart the postfix service after changing any options in the configuration files under the `/etc/postfix` directory in order for those changes to take effect:

```bash
~]# service postfix restart
```

**12.3.1.2. Basic Postfix Configuration**

By default, Postfix does not accept network connections from any host other than the local host. Perform the following steps as root to enable mail delivery for other hosts on the network:

- Edit the `/etc/postfix/main.cf` file with a text editor, such as **vi**.

- Uncomment the `mydomain` line by removing the hash sign (#), and replace `domain.tld` with the domain the mail server is servicing, such as `example.com`.

- Uncomment the `myorigin = $mydomain` line.

- Uncomment the `myhostname` line, and replace `host.domain.tld` with the hostname for the machine.

- Uncomment the `mydestination = $myhostname, localhost.$mydomain` line.

- Uncomment the `mynetworks` line, and replace `168.100.189.0/28` with a valid network setting for hosts that can connect to the server.

- Uncomment the `inet_interfaces = all` line.

- Comment the `inet_interfaces = localhost` line.

- Restart the postfix service.

Once these steps are complete, the host accepts outside emails for delivery.

Postfix has a large assortment of configuration options. One of the best ways to learn how to configure Postfix is to read the comments within the `/etc/postfix/main.cf` configuration file. Additional resources including information about Postfix configuration, SpamAssassin integration, or detailed descriptions of the `/etc/postfix/main.cf` parameters are available online at [http://www.postfix.org/](http://www.postfix.org/).
12.3.1.3. Using Postfix with LDAP

Postfix can use an LDAP directory as a source for various lookup tables (e.g.: aliases, virtual, canonical, etc.). This allows LDAP to store hierarchical user information and Postfix to only be given the result of LDAP queries when needed. By not storing this information locally, administrators can easily maintain it.

12.3.1.3.1. The /etc/aliases lookup example

The following is a basic example for using LDAP to look up the /etc/aliases file. Make sure your /etc/postfix/main.cf contains the following:

```
alias_maps = hash:/etc/aliases, ldap:/etc/postfix/ldap-aliases.cf
```

Create a /etc/postfix/ldap-aliases.cf file if you do not have one created already and make sure it contains the following:

```
server_host = ldap.example.com
search_base = dc=example, dc=com
```

where ldap.example.com, example, and com are parameters that need to be replaced with specification of an existing available LDAP server.

**Note**

The /etc/postfix/ldap-aliases.cf file can specify various parameters, including parameters that enable LDAP SSL and STARTTLS. For more information, refer to the ldap_table(5) man page.

12.3.2. Sendmail

Sendmail's core purpose, like other MTAs, is to safely transfer email among hosts, usually using the SMTP protocol. However, Sendmail is highly configurable, allowing control over almost every aspect of how email is handled, including the protocol used. Many system administrators elect to use Sendmail as their MTA due to its power and scalability.

12.3.2.1. Purpose and Limitations

It is important to be aware of what Sendmail is and what it can do, as opposed to what it is not. In these days of monolithic applications that fulfill multiple roles, Sendmail may seem like the only application needed to run an email server within an organization. Technically, this is true, as Sendmail can spool mail to each users' directory and deliver outbound mail for users. However, most users actually require much more than simple email delivery. Users usually want to interact with their email using an MUA, that uses POP or IMAP, to download their messages to their local machine. Or, they may prefer a Web interface to gain access to their mailbox. These other applications can work in conjunction with Sendmail, but they actually exist for different reasons and can operate separately from one another.

It is beyond the scope of this section to go into all that Sendmail should or could be configured to do. With literally hundreds of different options and rule sets, entire volumes have been dedicated to helping explain everything that can be done and how to fix things that go wrong. Refer to the Section 12.6, “Additional Resources” for a list of Sendmail resources.
Chapter 12. Email

This section reviews the files installed with Sendmail by default and reviews basic configuration changes, including how to stop unwanted email (spam) and how to extend Sendmail with the Lightweight Directory Access Protocol (LDAP).

12.3.2.2. The Default Sendmail Installation

In order to use Sendmail, first ensure the sendmail package is installed on your system by running, as root:

```bash
~# yum install sendmail
```

In order to configure Sendmail, ensure the sendmail-cf package is installed on your system by running, as root:

```bash
~# yum install sendmail-cf
```

For more information on installing packages with Yum, refer to Section 1.2.2, "Installing".

Before using Sendmail, the default MTA has to be switched from Postfix. For more information how to switch the default MTA refer to Section 12.3, "Mail Transport Agents".

The Sendmail executable is /usr/sbin/sendmail.

Sendmail's lengthy and detailed configuration file is /etc/mail/sendmail.cf. Avoid editing the sendmail.cf file directly. To make configuration changes to Sendmail, edit the /etc/mail/sendmail.mc file, back up the original /etc/mail/sendmail.cf, and use the following alternatives to generate a new configuration file:

- Use the included makefile in /etc/mail/ (~# make all -C /etc/mail/) to create a new /etc/mail/sendmail.cf configuration file. All other generated files in /etc/mail (db files) will be regenerated if needed. The old makemap commands are still usable. The make command will automatically be used by service sendmail start | restart | reload.

- Alternatively you may use the m4 macro processor to create a new /etc/mail/sendmail.cf. The m4 macro processor is not installed by default. Before using it to create /etc/mail/sendmail.cf, install the m4 package as root:

  ```bash
  ~# yum install m4
  ```

More information on configuring Sendmail can be found in Section 12.3.2.3, "Common Sendmail Configuration Changes".

Various Sendmail configuration files are installed in the /etc/mail/ directory including:

- access — Specifies which systems can use Sendmail for outbound email.

- domaintable — Specifies domain name mapping.

- local-host-names — Specifies aliases for the host.

- mailertable — Specifies instructions that override routing for particular domains.

- virtusertable — Specifies a domain-specific form of aliasing, allowing multiple virtual domains to be hosted on one machine.

Several of the configuration files in /etc/mail/, such as access, domaintable, mailertable and virtusertable, must actually store their information in database files before Sendmail can use...
any configuration changes. To include any changes made to these configurations in their database files, run the following command, as root:

```
~# makemap hash /etc/mail/<name> < /etc/mail/<name>
```

where `<name>` represents the name of the configuration file to be updated. You may also restart the sendmail service for the changes to take effect by running:

```
~# service sendmail restart
```

For example, to have all emails addressed to the `example.com` domain delivered to `bob@other-example.com`, add the following line to the `virtusertable` file:

```
@example.com bob@other-example.com
```

To finalize the change, the `virtusertable.db` file must be updated:

```
~# makemap hash /etc/mail/virtusertable < /etc/mail/virtusertable
```

Sendmail will create an updated `virtusertable.db` file containing the new configuration.

### 12.3.2.3. Common Sendmail Configuration Changes

When altering the Sendmail configuration file, it is best not to edit an existing file, but to generate an entirely new `/etc/mail/sendmail.cf` file.

**Caution**

Before changing the `sendmail.cf` file, it is a good idea to create a backup copy.

To add the desired functionality to Sendmail, edit the `/etc/mail/sendmail.mc` file as root. Once you are finished, restart the sendmail service and, if the `m4` package is installed, the `m4` macro processor will automatically generate a new `sendmail.cf` configuration file:

```
~# service sendmail restart
```

**Important**

The default `sendmail.cf` file does not allow Sendmail to accept network connections from any host other than the local computer. To configure Sendmail as a server for other clients, edit the `/etc/mail/sendmail.mc` file, and either change the address specified in the `Addr=` option of the `DAEMON_OPTIONS` directive from `127.0.0.1` to the IP address of an active network device or comment out the `DAEMON_OPTIONS` directive all together by placing `dnl` at the beginning of the line. When finished, regenerate `/etc/mail/sendmail.cf` by restarting the service:

```
~# service sendmail restart
```
Chapter 12. Email

The default configuration which ships with Red Hat Enterprise Linux works for most SMTP-only sites. However, it does not work for UUCP (UNIX-to-UNIX Copy Protocol) sites. If using UUCP mail transfers, the `/etc/mail/sendmail.mc` file must be reconfigured and a new `/etc/mail/sendmail.cf` file must be generated.

Consult the `/usr/share/sendmail-cf/README` file before editing any files in the directories under the `/usr/share/sendmail-cf` directory, as they can affect the future configuration of the `/etc/mail/sendmail.cf` file.

12.3.2.4. Masquerading

One common Sendmail configuration is to have a single machine act as a mail gateway for all machines on the network. For instance, a company may want to have a machine called `mail.example.com` that handles all of their email and assigns a consistent return address to all outgoing mail.

In this situation, the Sendmail server must masquerade the machine names on the company network so that their return address is `user@example.com` instead of `user@host.example.com`.

To do this, add the following lines to `/etc/mail/sendmail.mc`:

```plaintext
FEATURE(always_add_domain)dnl
FEATURE(`masquerade_entire_domain')dnl
FEATURE(`masquerade_envelope')dnl
FEATURE(`allmasquerade')dnl
MASQUERADE_AS(`bigcorp.com.')dnl
MASQUERADE_DOMAIN(`bigcorp.com.')dnl
MASQUERADE_AS(bigcorp.com)dnl
```

After generating a new `sendmail.cf` using the `m4` macro processor, this configuration makes all mail from inside the network appear as if it were sent from `bigcorp.com`.

12.3.2.5. Stopping Spam

Email spam can be defined as unnecessary and unwanted email received by a user who never requested the communication. It is a disruptive, costly, and widespread abuse of Internet communication standards.

Sendmail makes it relatively easy to block new spamming techniques being employed to send junk email. It even blocks many of the more usual spamming methods by default. Main anti-spam features available in sendmail are header checks, relaying denial (default from version 8.9), access database and sender information checks.

For example, forwarding of SMTP messages, also called relaying, has been disabled by default since Sendmail version 8.9. Before this change occurred, Sendmail directed the mail host (`x.edu`) to accept messages from one party (`y.com`) and sent them to a different party (`z.net`). Now, however, Sendmail must be configured to permit any domain to relay mail through the server. To configure relay domains, edit the `/etc/mail/relay-domains` file and restart Sendmail

```
~]# service sendmail restart
```

However, many times users are bombarded with spam from other servers throughout the Internet. In these instances, Sendmail's access control features available through the `/etc/mail/access` file can be used to prevent connections from unwanted hosts. The following example illustrates how this file can be used to both block and specifically allow access to the Sendmail server:
This example shows that any email sent from `badspammer.com` is blocked with a 550 RFC-821 compliant error code, with a message sent back to the spammer. Email sent from the `tux.badspammer.com` sub-domain, is accepted. The last line shows that any email sent from the 10.0.*.* network can be relayed through the mail server.

Because the `/etc/mail/access.db` file is a database, use the `makemap` command to update any changes. Do this using the following command as root:

```
~]# makemap hash /etc/mail/access < /etc/mail/access
```

Message header analysis allows you to reject mail based on header contents. SMTP servers store information about an email’s journey in the message header. As the message travels from one MTA to another, each puts in a `Received` header above all the other `Received` headers. It is important to note that this information may be altered by spammers.

The above examples only represent a small part of what Sendmail can do in terms of allowing or blocking access. Refer to the `/usr/share/sendmail-cf/README` for more information and examples.

Since Sendmail calls the Procmail MDA when delivering mail, it is also possible to use a spam filtering program, such as SpamAssassin, to identify and file spam for users. Refer to Section 12.4.2.6, “Spam Filters” for more information about using SpamAssassin.

### 12.3.2.6. Using Sendmail with LDAP

Using LDAP is a very quick and powerful way to find specific information about a particular user from a much larger group. For example, an LDAP server can be used to look up a particular email address from a common corporate directory by the user’s last name. In this kind of implementation, LDAP is largely separate from Sendmail, with LDAP storing the hierarchical user information and Sendmail only being given the result of LDAP queries in pre-addressed email messages.

However, Sendmail supports a much greater integration with LDAP, where it uses LDAP to replace separately maintained files, such as `/etc/aliases` and `/etc/mail/virtusertables`, on different mail servers that work together to support a medium- to enterprise-level organization. In short, LDAP abstracts the mail routing level from Sendmail and its separate configuration files to a powerful LDAP cluster that can be leveraged by many different applications.

The current version of Sendmail contains support for LDAP. To extend the Sendmail server using LDAP, first get an LDAP server, such as OpenLDAP, running and properly configured. Then edit the `/etc/mail/sendmail.mc` to include the following:

```
LDAPROUTE_DOMAIN('yourdomain.com')dnl
FEATURE('ldap_routing')dnl
```
Chapter 12. Email

Note

This is only for a very basic configuration of Sendmail with LDAP. The configuration can differ greatly from this depending on the implementation of LDAP, especially when configuring several Sendmail machines to use a common LDAP server.

Consult /usr/share/sendmail-cf/README for detailed LDAP routing configuration instructions and examples.

Next, recreate the /etc/mail/sendmail.cf file by running the m4 macro processor and again restarting Sendmail. Refer to Section 12.3.2.3, “Common Sendmail Configuration Changes” for instructions.

12.3.3. Fetchmail

Fetchmail is an MTA which retrieves email from remote servers and delivers it to the local MTA. Many users appreciate the ability to separate the process of downloading their messages located on a remote server from the process of reading and organizing their email in an MUA. Designed with the needs of dial-up users in mind, Fetchmail connects and quickly downloads all of the email messages to the mail spool file using any number of protocols, including POP3 and IMAP. It can even forward email messages to an SMTP server, if necessary.

Note: Installing the fetchmail package

In order to use Fetchmail, first ensure the fetchmail package is installed on your system by running, as root:

```
~]# yum install fetchmail
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

Fetchmail is configured for each user through the use of a .fetchmailrc file in the user's home directory. If it does not already exist, create the .fetchmailrc file in your home directory

Using preferences in the .fetchmailrc file, Fetchmail checks for email on a remote server and downloads it. It then delivers it to port 25 on the local machine, using the local MTA to place the email in the correct user's spool file. If Procmail is available, it is launched to filter the email and place it in a mailbox so that it can be read by an MUA.

12.3.3.1. Fetchmail Configuration Options

Although it is possible to pass all necessary options on the command line to check for email on a remote server when executing Fetchmail, using a .fetchmailrc file is much easier. Place any desired configuration options in the .fetchmailrc file for those options to be used each time the fetchmail command is issued. It is possible to override these at the time Fetchmail is run by specifying that option on the command line.

A user's .fetchmailrc file contains three classes of configuration options:

- **global options** — Gives Fetchmail instructions that control the operation of the program or provide settings for every connection that checks for email.
• **server options** — Specifies necessary information about the server being polled, such as the hostname, as well as preferences for specific email servers, such as the port to check or number of seconds to wait before timing out. These options affect every user using that server.

• **user options** — Contains information, such as username and password, necessary to authenticate and check for email using a specified email server.

Global options appear at the top of the `.fetchmailrc` file, followed by one or more server options, each of which designate a different email server that Fetchmail should check. User options follow server options for each user account checking that email server. Like server options, multiple user options may be specified for use with a particular server as well as to check multiple email accounts on the same server.

Server options are called into service in the `.fetchmailrc` file by the use of a special option verb, `poll` or `skip`, that precedes any of the server information. The `poll` action tells Fetchmail to use this server option when it is run, which checks for email using the specified user options. Any server options after a `skip` action, however, are not checked unless this server's hostname is specified when Fetchmail is invoked. The `skip` option is useful when testing configurations in the `.fetchmailrc` file because it only checks skipped servers when specifically invoked, and does not affect any currently working configurations.

The following is a sample example of a `.fetchmailrc` file:

```plaintext
set postmaster "user1"
set bouncemail

poll pop.domain.com proto pop3
  user 'user1' there with password 'secret' is user1 here

poll mail.domain2.com
  user 'user5' there with password 'secret2' is user1 here
  user 'user7' there with password 'secret3' is user1 here
```

In this example, the global options specify that the user is sent email as a last resort (`postmaster` option) and all email errors are sent to the postmaster instead of the sender (`bouncemail` option). The `set` action tells Fetchmail that this line contains a global option. Then, two email servers are specified, one set to check using POP3, the other for trying various protocols to find one that works. Two users are checked using the second server option, but all email found for any user is sent to `user1`'s mail spool. This allows multiple mailboxes to be checked on multiple servers, while appearing in a single MUA inbox. Each user's specific information begins with the `user` action.

**Note**

Users are not required to place their password in the `.fetchmailrc` file. Omitting the `with password '<password>'` section causes Fetchmail to ask for a password when it is launched.

Fetchmail has numerous global, server, and local options. Many of these options are rarely used or only apply to very specific situations. The `fetchmail` man page explains each option in detail, but the most common ones are listed in the following three sections.

### 12.3.3.2. Global Options

Each global option should be placed on a single line after a `set` action.

- **daemon `<seconds>`** — Specifies daemon-mode, where Fetchmail stays in the background.
  
  Replace `<seconds>` with the number of seconds Fetchmail is to wait before polling the server.
**Chapter 12. Email**

- **postmaster** — Specifies a local user to send mail to in case of delivery problems.

- **syslog** — Specifies the log file for errors and status messages. By default, this is `/var/log/maillog`.

### 12.3.3.3. Server Options

Server options must be placed on their own line in `.fetchmailrc` after a `poll` or `skip` action.

- **auth <auth-type>** — Replace `<auth-type>` with the type of authentication to be used. By default, `password` authentication is used, but some protocols support other types of authentication, including `kerberos_v5`, `kerberos_v4`, and `ssh`. If the any authentication type is used, Fetchmail first tries methods that do not require a password, then methods that mask the password, and finally attempts to send the password unencrypted to authenticate to the server.

- **interval <number>** — Polls the specified server every `<number>` of times that it checks for email on all configured servers. This option is generally used for email servers where the user rarely receives messages.

- **port <port-number>** — Replace `<port-number>` with the port number. This value overrides the default port number for the specified protocol.

- **proto <protocol>** — Replace `<protocol>` with the protocol, such as `pop3` or `imap`, to use when checking for messages on the server.

- **timeout <seconds>** — Replace `<seconds>` with the number of seconds of server inactivity after which Fetchmail gives up on a connection attempt. If this value is not set, a default of `300` seconds is assumed.

### 12.3.3.4. User Options

User options may be placed on their own lines beneath a server option or on the same line as the server option. In either case, the defined options must follow the `user` option (defined below).

- **fetchall** — Orders Fetchmail to download all messages in the queue, including messages that have already been viewed. By default, Fetchmail only pulls down new messages.

- **fetchlimit <number>** — Replace `<number>` with the number of messages to be retrieved before stopping.

- **flush** — Deletes all previously viewed messages in the queue before retrieving new messages.

- **limit <max-number-bytes>** — Replace `<max-number-bytes>` with the maximum size in bytes that messages are allowed to be when retrieved by Fetchmail. This option is useful with slow network links, when a large message takes too long to download.

- **password '<password>'** — Replace `<password>` with the user's password.

- **preconnect "<command>"** — Replace `<command>` with a command to be executed before retrieving messages for the user.

- **postconnect "<command>"** — Replace `<command>` with a command to be executed after retrieving messages for the user.

- **ssl** — Activates SSL encryption.

- **user "<username>"** — Replace `<username>` with the username used by Fetchmail to retrieve messages. This option must precede all other user options.
12.3.3.5. Fetchmail Command Options

Most Fetchmail options used on the command line when executing the *fetchmail* command mirror the `.fetchmailrc` configuration options. In this way, Fetchmail may be used with or without a configuration file. These options are not used on the command line by most users because it is easier to leave them in the `.fetchmailrc` file.

There may be times when it is desirable to run the *fetchmail* command with other options for a particular purpose. It is possible to issue command options to temporarily override a `.fetchmailrc` setting that is causing an error, as any options specified at the command line override configuration file options.

12.3.3.6. Informational or Debugging Options

Certain options used after the *fetchmail* command can supply important information.

- `--configdump` — Displays every possible option based on information from `.fetchmailrc` and Fetchmail defaults. No email is retrieved for any users when using this option.

- `-s` — Executes Fetchmail in silent mode, preventing any messages, other than errors, from appearing after the *fetchmail* command.

- `-v` — Executes Fetchmail in verbose mode, displaying every communication between Fetchmail and remote email servers.

- `-V` — Displays detailed version information, lists its global options, and shows settings to be used with each user, including the email protocol and authentication method. No email is retrieved for any users when using this option.

12.3.3.7. Special Options

These options are occasionally useful for overriding defaults often found in the `.fetchmailrc` file.

- `-a` — Fetchmail downloads all messages from the remote email server, whether new or previously viewed. By default, Fetchmail only downloads new messages.

- `-k` — Fetchmail leaves the messages on the remote email server after downloading them. This option overrides the default behavior of deleting messages after downloading them.

- `-l <max-number-bytes>` — Fetchmail does not download any messages over a particular size and leaves them on the remote email server.

- `--quit` — Quits the Fetchmail daemon process.

More commands and `.fetchmailrc` options can be found in the *fetchmail* man page.

12.3.4. Mail Transport Agent (MTA) Configuration

A Mail Transport Agent (MTA) is essential for sending email. A Mail User Agent (MUA) such as Evolution, Thunderbird, and Mutt, is used to read and compose email. When a user sends an email from an MUA, the message is handed off to the MTA, which sends the message through a series of MTAs until it reaches its destination.

Even if a user does not plan to send email from the system, some automated tasks or system programs might use the `/bin/mail` command to send email containing log messages to the root user of the local system.
Red Hat Enterprise Linux 6 provides two MTAs: Postfix and Sendmail. If both are installed, Postfix is the default MTA.

### 12.4. Mail Delivery Agents

Red Hat Enterprise Linux includes two primary MDAs, Procmail and `mail`. Both of the applications are considered LDAs and both move email from the MTA’s spool file into the user’s mailbox. However, Procmail provides a robust filtering system.

This section details only Procmail. For information on the `mail` command, consult its man page (`man mail`).

Procmail delivers and filters email as it is placed in the mail spool file of the localhost. It is powerful, gentle on system resources, and widely used. Procmail can play a critical role in delivering email to be read by email client applications.

Procmail can be invoked in several different ways. Whenever an MTA places an email into the mail spool file, Procmail is launched. Procmail then filters and files the email for the MUA and quits. Alternatively, the MUA can be configured to execute Procmail any time a message is received so that messages are moved into their correct mailboxes. By default, the presence of `/etc/procmailrc` or of a `~/.procmailrc` file (also called an rc file) in the user's home directory invokes Procmail whenever an MTA receives a new message.

By default, no system-wide rc files exist in the `/etc` directory and no `.procmailrc` files exist in any user's home directory. Therefore, to use Procmail, each user must construct a `.procmailrc` file with specific environment variables and rules.

Whether Procmail acts upon an email message depends upon whether the message matches a specified set of conditions or recipes in the rc file. If a message matches a recipe, then the email is placed in a specified file, is deleted, or is otherwise processed.

When Procmail starts, it reads the email message and separates the body from the header information. Next, Procmail looks for a `/etc/procmailrc` file and rc files in the `/etc/procmailrcs` directory for default, system-wide, Procmail environmental variables and recipes. Procmail then searches for a `.procmailrc` file in the user's home directory. Many users also create additional rc files for Procmail that are referred to within the `.procmailrc` file in their home directory.

### 12.4.1. Procmail Configuration

The Procmail configuration file contains important environmental variables. These variables specify things such as which messages to sort and what to do with the messages that do not match any recipes.

These environmental variables usually appear at the beginning of the `~/.procmailrc` file in the following format:

```
<env-variable>="<value>"
```

In this example, `<env-variable>` is the name of the variable and `<value>` defines the variable.

There are many environment variables not used by most Procmail users and many of the more important environment variables are already defined by a default value. Most of the time, the following variables are used:
Procmail Recipes

- **DEFAULT** — Sets the default mailbox where messages that do not match any recipes are placed.

  The default DEFAULT value is the same as $ORGMAIL.

- **INCLUDERC** — Specifies additional rc files containing more recipes for messages to be checked against. This breaks up the Procmail recipe lists into individual files that fulfill different roles, such as blocking spam and managing email lists, that can then be turned off or on by using comment characters in the user's ~/.procmailrc file.

  For example, lines in a user's .procmailrc file may look like this:

  ```
  MAILDIR=$HOME/Msgs INCLUDERC=$MAILDIR/lists.rc INCLUDERC=$MAILDIR/spam.rc
  ```

  To turn off Procmail filtering of email lists but leaving spam control in place, comment out the first INCLUDERC line with a hash sign (#).

- **LOCKSLEEP** — Sets the amount of time, in seconds, between attempts by Procmail to use a particular lockfile. The default is 8 seconds.

- **LOCKTIMEOUT** — Sets the amount of time, in seconds, that must pass after a lockfile was last modified before Procmail assumes that the lockfile is old and can be deleted. The default is 1024 seconds.

- **LOGFILE** — The file to which any Procmail information or error messages are written.

- **MAILDIR** — Sets the current working directory for Procmail. If set, all other Procmail paths are relative to this directory.

- **ORGMAIL** — Specifies the original mailbox, or another place to put the messages if they cannot be placed in the default or recipe-required location.

  By default, a value of /var/spool/mail/$LOGNAME is used.

- **SUSPEND** — Sets the amount of time, in seconds, that Procmail pauses if a necessary resource, such as swap space, is not available.

- **SWITCHRC** — Allows a user to specify an external file containing additional Procmail recipes, much like the INCLUDERC option, except that recipe checking is actually stopped on the referring configuration file and only the recipes on the SWITCHRC-specified file are used.

- **VERBOSE** — Causes Procmail to log more information. This option is useful for debugging.

Other important environmental variables are pulled from the shell, such as LOGNAME, which is the login name; HOME, which is the location of the home directory; and SHELL, which is the default shell.

A comprehensive explanation of all environments variables, as well as their default values, is available in the procmailrc man page.

### 12.4.2. Procmail Recipes

New users often find the construction of recipes the most difficult part of learning to use Procmail. To some extent, this is understandable, as recipes do their message matching using regular expressions, which is a particular format used to specify qualifications for a matching string. However, regular expressions are not very difficult to construct and even less difficult to understand when read. Additionally, the consistency of the way Procmail recipes are written, regardless of regular expressions, makes it easy to learn by example. To see example Procmail recipes, refer to Section 12.4.2.5, “Recipe Examples.”
Chapter 12. Email

Procmail recipes take the following form:

\[
\text{:0<flags>: <lockfile-name> * <special-condition-character>}
\text{condition-1> * <special-condition-character>}
\text{condition-2> * <special-condition-character>}
\text{condition-N>}
\text{<special-action-character>}
\text{<action-to-perform>}
\]

The first two characters in a Procmail recipe are a colon and a zero. Various flags can be placed after the zero to control how Procmail processes the recipe. A colon after the \text{<flags> section} specifies that a lockfile is created for this message. If a lockfile is created, the name can be specified by replacing \text{<lockfile-name> .}

A recipe can contain several conditions to match against the message. If it has no conditions, every message matches the recipe. Regular expressions are placed in some conditions to facilitate message matching. If multiple conditions are used, they must all match for the action to be performed. Conditions are checked based on the flags set in the recipe's first line. Optional special characters placed after the asterisk character (\text{*}) can further control the condition.

The \text{<action-to-perform> argument} specifies the action taken when the message matches one of the conditions. There can only be one action per recipe. In many cases, the name of a mailbox is used here to direct matching messages into that file, effectively sorting the email. Special action characters may also be used before the action is specified. Refer to Section 12.4.2.4, “Special Conditions and Actions” for more information.

12.4.2.1. Delivering vs. Non-Delivering Recipes

The action used if the recipe matches a particular message determines whether it is considered a delivering or non-delivering recipe. A delivering recipe contains an action that writes the message to a file, sends the message to another program, or forwards the message to another email address. A non-delivering recipe covers any other actions, such as a nesting block. A nesting block is a set of actions, contained in braces \{ }, that are performed on messages which match the recipe's conditions. Nesting blocks can be nested inside one another, providing greater control for identifying and performing actions on messages.

When messages match a delivering recipe, Procmail performs the specified action and stops comparing the message against any other recipes. Messages that match non-delivering recipes continue to be compared against other recipes.

12.4.2.2. Flags

Flags are essential to determine how or if a recipe's conditions are compared to a message. The following flags are commonly used:

- \text{A} — Specifies that this recipe is only used if the previous recipe without an \text{A} or \text{a} flag also matched this message.
- \text{a} — Specifies that this recipe is only used if the previous recipe with an \text{A} or \text{a} flag also matched this message \text{and} was successfully completed.
- \text{B} — Parses the body of the message and looks for matching conditions.
- \text{b} — Uses the body in any resulting action, such as writing the message to a file or forwarding it. This is the default behavior.
• **c** — Generates a carbon copy of the email. This is useful with delivering recipes, since the required action can be performed on the message and a copy of the message can continue being processed in the rc files.

• **D** — Makes the egrep comparison case-sensitive. By default, the comparison process is not case-sensitive.

• **E** — While similar to the A flag, the conditions in the recipe are only compared to the message if the immediately preceding the recipe without an E flag did not match. This is comparable to an else action.

• **e** — The recipe is compared to the message only if the action specified in the immediately preceding recipe fails.

• **f** — Uses the pipe as a filter.

• **H** — Parses the header of the message and looks for matching conditions. This is the default behavior.

• **h** — Uses the header in a resulting action. This is the default behavior.

• **w** — Tells Procmail to wait for the specified filter or program to finish, and reports whether or not it was successful before considering the message filtered.

• **W** — Is identical to w except that "Program failure" messages are suppressed.

For a detailed list of additional flags, refer to the procmailrc man page.

12.4.2.3. Specifying a Local Lockfile

Lockfiles are very useful with Procmail to ensure that more than one process does not try to alter a message simultaneously. Specify a local lockfile by placing a colon (: ) after any flags on a recipe's first line. This creates a local lockfile based on the destination file name plus whatever has been set in the LOCKEXT global environment variable.

Alternatively, specify the name of the local lockfile to be used with this recipe after the colon.

12.4.2.4. Special Conditions and Actions

Special characters used before Procmail recipe conditions and actions change the way they are interpreted.

The following characters may be used after the asterisk character (*) at the beginning of a recipe's condition line:

• **!** — In the condition line, this character inverts the condition, causing a match to occur only if the condition does not match the message.

• **<** — Checks if the message is under a specified number of bytes.

• **>** — Checks if the message is over a specified number of bytes.

The following characters are used to perform special actions:

• **!** — In the action line, this character tells Procmail to forward the message to the specified email addresses.
Chapter 12. Email

- $ — Refers to a variable set earlier in the rc file. This is often used to set a common mailbox that is referred to by various recipes.

- | — Starts a specified program to process the message.

- { and } — Constructs a nesting block, used to contain additional recipes to apply to matching messages.

If no special character is used at the beginning of the action line, Procmail assumes that the action line is specifying the mailbox in which to write the message.

12.4.2.5. Recipe Examples

Procmail is an extremely flexible program, but as a result of this flexibility, composing Procmail recipes from scratch can be difficult for new users.

The best way to develop the skills to build Procmail recipe conditions stems from a strong understanding of regular expressions combined with looking at many examples built by others. A thorough explanation of regular expressions is beyond the scope of this section. The structure of Procmail recipes and useful sample Procmail recipes can be found at various places on the Internet (such as http://www.iki.fi/era/procmail/links.html). The proper use and adaptation of regular expressions can be derived by viewing these recipe examples. In addition, introductory information about basic regular expression rules can be found in the grep man page.

The following simple examples demonstrate the basic structure of Procmail recipes and can provide the foundation for more intricate constructions.

A basic recipe may not even contain conditions, as is illustrated in the following example:

```
:0: new-mail.spool
```

The first line specifies that a local lockfile is to be created but does not specify a name, so Procmail uses the destination file name and appends the value specified in the LOCKEXT environment variable. No condition is specified, so every message matches this recipe and is placed in the single spool file called new-mail.spool, located within the directory specified by the MAILDIR environment variable. An MUA can then view messages in this file.

A basic recipe, such as this, can be placed at the end of all rc files to direct messages to a default location.

The following example matched messages from a specific email address and throws them away.

```
:0 * ^From: spammer@domain.com /dev/null
```

With this example, any messages sent by spammer@domain.com are sent to the /dev/null device, deleting them.
Caution

Be certain that rules are working as intended before sending messages to /dev/null for permanent deletion. If a recipe inadvertently catches unintended messages, and those messages disappear, it becomes difficult to troubleshoot the rule.

A better solution is to point the recipe's action to a special mailbox, which can be checked from time to time to look for false positives. Once satisfied that no messages are accidentally being matched, delete the mailbox and direct the action to send the messages to /dev/null.

The following recipe grabs email sent from a particular mailing list and places it in a specified folder.

```plaintext
:0: *(From|Cc|To).*tux-lug tuxlug
```

Any messages sent from the tux-lug@domain.com mailing list are placed in the tuxlug mailbox automatically for the MUA. Note that the condition in this example matches the message if it has the mailing list's email address on the From, Cc, or To lines.

Consult the many Procmail online resources available in Section 12.6, “Additional Resources” for more detailed and powerful recipes.

12.4.2.6. Spam Filters

Because it is called by Sendmail, Postfix, and Fetchmail upon receiving new emails, Procmail can be used as a powerful tool for combating spam.

This is particularly true when Procmail is used in conjunction with SpamAssassin. When used together, these two applications can quickly identify spam emails, and sort or destroy them.

SpamAssassin uses header analysis, text analysis, blacklists, a spam-tracking database, and self-learning Bayesian spam analysis to quickly and accurately identify and tag spam.

Note: Installing the spamassassin package

In order to use SpamAssassin, first ensure the spamassassin package is installed on your system by running, as root:

```bash
~]$ yum install spamassassin
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

The easiest way for a local user to use SpamAssassin is to place the following line near the top of the ~/.procmailrc file:

```plaintext
INCLUDERC=/etc/mail/spamassassin/spamassassin-default.rc
```

The /etc/mail/spamassassin/spamassassin-default.rc contains a simple Procmail rule that activates SpamAssassin for all incoming email. If an email is determined to be spam, it is tagged in the header as such and the title is prepended with the following pattern:
Chapter 12. Email

*****SPAM*****

The message body of the email is also prepended with a running tally of what elements caused it to be diagnosed as spam.

To file email tagged as spam, a rule similar to the following can be used:

```
:0 Hw * ^X-Spam-Status: Yes spam
```

This rule files all email tagged in the header as spam into a mailbox called spam.

Since SpamAssassin is a Perl script, it may be necessary on busy servers to use the binary SpamAssassin daemon (spamd) and the client application (spamd). Configuring SpamAssassin this way, however, requires root access to the host.

To start the spamd daemon, type the following command:

```
~]# service spamassassin start
```

To start the SpamAssassin daemon when the system is booted, use an initscript utility, such as the Services Configuration Tool (system-config-services), to turn on the spamassassin service. Refer to Chapter 7, Controlling Access to Services for more information about starting and stopping services.

To configure Procmail to use the SpamAssassin client application instead of the Perl script, place the following line near the top of the ~/.procmailrc file. For a system-wide configuration, place it in /etc/procmailrc:

```
INCLUDERC=/etc/mail/spamassassin/spamassassin-spamc.rc
```

12.5. Mail User Agents

Red Hat Enterprise Linux offers a variety of email programs, both, graphical email client programs, such as Evolution, and text-based email programs such as mutt.

The remainder of this section focuses on securing communication between a client and a server.

12.5.1. Securing Communication

Popular MUAs included with Red Hat Enterprise Linux, such as Evolution and mutt offer SSL-encrypted email sessions.

Like any other service that flows over a network unencrypted, important email information, such as usernames, passwords, and entire messages, may be intercepted and viewed by users on the network. Additionally, since the standard POP and IMAP protocols pass authentication information unencrypted, it is possible for an attacker to gain access to user accounts by collecting usernames and passwords as they are passed over the network.

12.5.1.1. Secure Email Clients

Most Linux MUAs designed to check email on remote servers support SSL encryption. To use SSL when retrieving email, it must be enabled on both the email client and the server.
SSL is easy to enable on the client-side, often done with the click of a button in the MUA’s configuration window or via an option in the MUA’s configuration file. Secure IMAP and POP have known port numbers (993 and 995, respectively) that the MUA uses to authenticate and download messages.

### 12.5.1.2. Securing Email Client Communications

Offering SSL encryption to IMAP and POP users on the email server is a simple matter.

First, create an SSL certificate. This can be done in two ways: by applying to a Certificate Authority (CA) for an SSL certificate or by creating a self-signed certificate.

**Caution**

Self-signed certificates should be used for testing purposes only. Any server used in a production environment should use an SSL certificate granted by a CA.

To create a self-signed SSL certificate for IMAP or POP, change to the `/etc/pki/dovecot/` directory, edit the certificate parameters in the `/etc/pki/dovecot/dovecot-openssl.conf` configuration file as you prefer, and type the following commands, as root:

```bash
dovecot]# rm -f certs/dovecot.pem private/dovecot.pem
dovecot]# /usr/libexec/dovecot/mkcert.sh
```

Once finished, make sure you have the following configurations in your `/etc/dovecot/conf.d/10-ssl.conf` file:

```bash
ssl_cert = </etc/pki/dovecot/certs/dovecot.pem
ssl_key = </etc/pki/dovecot/private/dovecot.pem
```

Execute the `service dovecot restart` command to restart the `dovecot` daemon.

Alternatively, the `stunnel` command can be used as an SSL encryption wrapper around the standard, non-secure connections to IMAP or POP services.

The `stunnel` utility uses external OpenSSL libraries included with Red Hat Enterprise Linux to provide strong cryptography and to protect the network connections. It is recommended to apply to a CA to obtain an SSL certificate, but it is also possible to create a self-signed certificate.

**Note: Installing the `stunnel` package**

In order to use `stunnel`, first ensure the `stunnel` package is installed on your system by running, as root:

```bash
[-]# yum install stunnel
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

To create a self-signed SSL certificate, change to the `/etc/pki/tls/certs/` directory, and type the following command:
Chapter 12. Email

certs]# make stunnel.pem

Answer all of the questions to complete the process.

Once the certificate is generated, create an stunnel configuration file, for example /etc/stunnel/mail.conf, with the following content:

```plaintext
cert = /etc/pki/tls/certs/stunnel.pem

[pop3s]
accept = 995
connect = 110

[imaps]
accept = 993
connect = 143
```

Once you start stunnel with the created configuration file using the /usr/bin/stunnel /etc/stunnel/mail.conf command, it will be possible to use an IMAP or a POP email client and connect to the email server using SSL encryption.

For more information on stunnel, refer to the stunnel man page or the documents in the /usr/share/doc/stunnel-<version-number> directory, where <version-number> is the version number of stunnel.

### 12.6. Additional Resources

The following is a list of additional documentation about email applications.

#### 12.6.1. Installed Documentation

- Information on configuring Sendmail is included with the sendmail and sendmail-cf packages.
  - `/usr/share/sendmail-cf/README` — Contains information on the m4 macro processor, file locations for Sendmail, supported mailers, how to access enhanced features, and more.

  In addition, the sendmail and aliases man pages contain helpful information covering various Sendmail options and the proper configuration of the Sendmail /etc/mail/aliases file.

- `/usr/share/doc/postfix-<version-number>` — Contains a large amount of information about ways to configure Postfix. Replace <version-number> with the version number of Postfix.

- `/usr/share/doc/fetchmail-<version-number>` — Contains a full list of Fetchmail features in the FEATURES file and an introductory FAQ document. Replace <version-number> with the version number of Fetchmail.

- `/usr/share/doc/procmail-<version-number>` — Contains a README file that provides an overview of Procmail, a FEATURES file that explores every program feature, and an FAQ file with answers to many common configuration questions. Replace <version-number> with the version number of Procmail.

  When learning how Procmail works and creating new recipes, the following Procmail man pages are invaluable:

  - procmail — Provides an overview of how Procmail works and the steps involved with filtering email.
Useful Websites

- **procmailrc** — Explains the rc file format used to construct recipes.
- **procmailex** — Gives a number of useful, real-world examples of Procmail recipes.
- **procmailsc** — Explains the weighted scoring technique used by Procmail to match a particular recipe to a message.
- **/usr/share/doc/spamassassin-<version-number>/** — Contains a large amount of information pertaining to SpamAssassin. Replace `<version-number>` with the version number of the spamassassin package.

### 12.6.2. Useful Websites

- **http://www.sendmail.org/** — Offers a thorough technical breakdown of Sendmail features, documentation and configuration examples.
- **http://www.sendmail.com/** — Contains news, interviews and articles concerning Sendmail, including an expanded view of the many options available.
- **http://www.postfix.org/** — The Postfix project home page contains a wealth of information about Postfix. The mailing list is a particularly good place to look for information.
- **http://fetchmail.berlios.de/** — The home page for Fetchmail, featuring an online manual, and a thorough FAQ.
- **http://www.procmail.org/** — The home page for Procmail with links to assorted mailing lists dedicated to Procmail as well as various FAQ documents.
- **http://www.uwasa.fi/~ts/info/proctips.html** — Contains dozens of tips that make using Procmail much easier. Includes instructions on how to test .procmailrc files and use Procmail scoring to decide if a particular action should be taken.
- **http://www.spamassassin.org/** — The official site of the SpamAssassin project.

### 12.6.3. Related Books

- **Sendmail Milters: A Guide for Fighting Spam** by Bryan Costales and Marcia Flynt; Addison-Wesley — A good Sendmail guide that can help you customise your mail filters.
- **Sendmail** by Bryan Costales with Eric Allman et al; O'Reilly & Associates — A good Sendmail reference written with the assistance of the original creator of Delivermail and Sendmail.
- **Removing the Spam: Email Processing and Filtering** by Geoff Mulligan; Addison-Wesley Publishing Company — A volume that looks at various methods used by email administrators using established tools, such as Sendmail and Procmail, to manage spam problems.
- **Internet Email Protocols: A Developer's Guide** by Kevin Johnson; Addison-Wesley Publishing Company — Provides a very thorough review of major email protocols and the security they provide.
- **Managing IMAP** by Dianna Mullet and Kevin Mullet; O'Reilly & Associates — Details the steps required to configure an IMAP server.
Part III. System Configuration

Part of a system administrator's job is configuring the system for various tasks, types of users, and hardware configurations. This section explains how to configure a Red Hat Enterprise Linux system.
Date and Time Configuration

This chapter covers setting the system date and time in Red Hat Enterprise Linux, both manually and using the Network Time Protocol (NTP), as well as setting the adequate time zone. Two methods are covered: setting the date and time using the Date/Time Properties tool, and doing so on the command line.

13.1. Date/Time Properties Tool

The Date/Time Properties tool allows the user to change the system date and time, to configure the time zone used by the system, and to set up the Network Time Protocol daemon to synchronize the system clock with a time server. Note that to use this application, you must be running the X Window System.

To start the tool, select System → Administration → Date & Time from the panel, or type the system-config-date command at a shell prompt (e.g., xterm or GNOME Terminal). Unless you are already authenticated, you will be prompted to enter the superuser password.

![Authentication Query](Figure 13.1. Authentication Query)

13.1.1. Date and Time Properties

As shown in Figure 13.2, "Date and Time Properties", the Date/Time Properties tool is divided into two separate tabs. The tab containing the configuration of the current date and time is shown by default.
Chapter 13. Date and Time Configuration

To set up your system manually, follow these steps:

1. **Change the current date.** Use the arrows to the left and right of the month and year to change the month and year respectively. Then click inside the calendar to select the day of the month.

2. **Change the current time.** Use the up and down arrow buttons beside the **Hour**, **Minute**, and **Second**, or replace the values directly.

Click the **OK** button to apply the changes and exit the application.

### 13.1.2. Network Time Protocol Properties

If you prefer an automatic setup, select the checkbox labeled **Synchronize date and time over the network** instead. This will display the list of available NTP servers as shown in *Figure 13.3, “Network Time Protocol Properties”*. 
13.1.3. Time Zone Properties

To configure the system time zone, click the **Time Zone** tab as shown in Figure 13.4, "Time Zone Properties".
Chapter 13. Date and Time Configuration

There are two common approaches to the time zone selection:

1. **Using the interactive map.** Click “zoom in” and “zoom out” buttons next to the map, or click on the map itself to zoom into the selected region. Then choose the city specific to your time zone. A red X appears and the time zone selection changes in the list below the map.

2. **Use the list below the map.** To make the selection easier, cities and countries are grouped within their specific continents. Note that non-geographic time zones have also been added to address needs in the scientific community.

If your system clock is set to use UTC, select the **System clock uses UTC** option. UTC stands for the **Universal Time, Coordinated**, also known as **Greenwich Mean Time (GMT)**. Other time zones are determined by adding or subtracting from the UTC time.

Click **OK** to apply the changes and exit the program.

### 13.2. Command Line Configuration

In case your system does not have the **Date/Time Properties** tool installed, or the **X Window Server** is not running, you will have to change the system date and time on the command line. Note that in order to perform actions described in this section, you have to be logged in as a superuser:

```
$ su -
Password:
```

### 13.2.1. Date and Time Setup

The **date** command allows the superuser to set the system date and time manually:
Network Time Protocol Setup

1. **Change the current date.** Type the command in the following form at a shell prompt, replacing the `YYYY` with a four-digit year, `MM` with a two-digit month, and `DD` with a two-digit day of the month:

   ```bash
   ~]# date +%D -s YYYY-MM-DD
   ```

   For example, to set the date to 2 June 2010, type:

   ```bash
   ~]# date +%D -s 2010-06-02
   ```

2. **Change the current time.** Use the following command, where `HH` stands for an hour, `MM` is a minute, and `SS` is a second, all typed in a two-digit form:

   ```bash
   ~]# date +%T -s HH:MM:SS
   ```

   If your system clock is set to use UTC (Coordinated Universal Time), add the following option:

   ```bash
   ~]# date +%T -s HH:MM:SS -u
   ```

   For instance, to set the system clock to 11:26 PM using the UTC, type:

   ```bash
   ~]# date +%T -s 23:26:00 -u
   ```

   You can check your current settings by typing `date` without any additional argument:

   ```bash
   -]£ date
   Wed Jun  2 11:58:48 CEST 2010
   ```

13.2.2. **Network Time Protocol Setup**

As opposed to the manual setup described above, you can also synchronize the system clock with a remote server over the Network Time Protocol (NTP). For the one-time synchronization only, use the `ntpd` command:

1. Firstly, check whether the selected NTP server is accessible:

   ```bash
   -]# ntpdate -q server_address
   ```

   For example:

   ```bash
   -]# ntpdate -q 0.rhel.pool.ntp.org
   ```

2. When you find a satisfactory server, run the `ntpd` command followed with on or more server addresses:

   ```bash
   -]# ntpdate server_address...
   ```

   For instance:
Chapter 13. Date and Time Configuration

```bash
-]# ntpdate 0.rhel.pool.ntp.org 1.rhel.pool.ntp.org
```

Unless an error message is displayed, the system time should now be set. You can check the current by setting typing `date` without any additional arguments as shown in Section 13.2.1, “Date and Time Setup”.

3. In most cases, these steps are sufficient. Only if you really need one or more system services to always use the correct time, enable running the `ntpdate` at boot time:

```bash
-]# chkconfig ntpdate on
```

For more information about system services and their setup, see Chapter 7, Controlling Access to Services.

**Note**

If the synchronization with the time server at boot time keeps failing, i.e., you find a relevant error message in the `/var/log/boot.log` system log, try to add the following line to `/etc/sysconfig/network`:

```
NETWORKWAIT=1
```

However, the more convenient way is to set the `ntpd` daemon to synchronize the time at boot time automatically:

1. Open the NTP configuration file `/etc/ntp.conf` in a text editor such as `vi` or `nano`, or create a new one if it does not already exist:

   ```bash
   -]# nano /etc/ntp.conf
   ```

2. Now add or edit the list of public NTP servers. If you are using Red Hat Enterprise Linux 6, the file should already contain the following lines, but feel free to change or expand these according to your needs:

   ```
   server 0.rhel.pool.ntp.org
   server 1.rhel.pool.ntp.org
   server 2.rhel.pool.ntp.org
   ```

**Tip**

To speed the initial synchronization up, add the `iburst` directive at the end of each server line:

```
server 0.rhel.pool.ntp.org iburst
server 1.rhel.pool.ntp.org iburst
server 2.rhel.pool.ntp.org iburst
```
3. Once you have the list of servers complete, in the same file, set the proper permissions, giving the unrestricted access to localhost only:

```plaintext
restrict default kod nomodify notrap nopeer noquery
restrict -6 default kod nomodify notrap nopeer noquery
restrict 127.0.0.1
restrict -6 ::1
```

4. Save all changes, exit the editor, and restart the NTP daemon:

```plaintext
-]# service ntpd restart
```

5. Make sure that `ntpd` daemon is started at boot time:

```plaintext
-]# chkconfig ntpd on
```
Keyboard Configuration

This chapter describes how to change the keyboard layout, as well as how to add the Keyboard Indicator applet to the panel. It also covers the option to enforce a typing break, and explains both advantages and disadvantages of doing so.

14.1. Changing the Keyboard Layout

The installation program allowed you to configure a keyboard layout for your system. However, the default settings may not always suit your current needs. To configure a different keyboard layout after the installation, use the Keyboard Preferences tool.

To open Keyboard Layout Preferences, select System → Preferences → Keyboard from the panel, and click the Layouts tab.

![Keyboard Layout Preferences](image)

Figure 14.1. Keyboard Layout Preferences

You will be presented with a list of available layouts. To add a new one, click the Add... button below the list, and you will be prompted to chose which layout you want to add.
Chapter 14. Keyboard Configuration

Currently, there are two ways how to chose the keyboard layout: you can either find it by the country it is associated with (the By country tab), or you can select it by the language (the By language tab). In either case, first select the desired country or language from the Country or Language pulldown menu, then specify the variant from the Variants menu. The preview of the layout changes immediately. To confirm the selection, click Add.

The layout should appear in the list. To make it the default, select the radio button next to its name. The changes take effect immediately. Note that there is a text-entry field at the bottom of the window where you can safely test your settings. Once you are satisfied, click Close to close the window.
Adding the Keyboard Layout Indicator

Suggestion: Disable Separate Layout for Each Window

By default, changing the keyboard layout affects the active window only. This means that if you change the layout and switch to another window, this window will use the old one, which might be confusing. To turn this unfortunate behavior off, unselect the **Separate layout for each window** check box.

Doing this has its drawbacks though, as you will no longer be able to chose the default layout by selecting the radio button as shown in *Figure 14.3, "Selecting the default layout"*. To make the layout the default, simply drag it at the beginning of the list.

14.2. Adding the Keyboard Layout Indicator

If you want to see what keyboard layout you are currently using, or you would like to switch between different layouts with a single mouse click, add the **Keyboard Indicator** applet to the panel. To do so, right-click the empty space on the main panel, and select the **Add to Panel...** option from the pulldown menu.

![Figure 14.5. Adding a new applet](image)

You will be presented with a list of available applets. Scroll through the list (or start typing "keyboard" to the search field at the top of the window), select **Keyboard Indicator**, and click the **Add** button.
Chapter 14. Keyboard Configuration

Figure 14.6. Selecting the **Keyboard Indicator**

The applet appears immediately, displaying the shortened name of the country the current layout is associated with. To display the actual variant, hover the pointer over the applet icon.

Figure 14.7. The **Keyboard Indicator** applet

### 14.3. Setting Up a Typing Break

Typing for a long period of time can be not only tiresome, but it can also increase the risk of serious health problems, such as the carpal tunnel syndrome. One way of preventing this is to configure the system to enforce the typing break. Simply select `System → Preferences → Keyboard` from the panel, click the **Typing Break** tab, and select the **Lock screen to enforce typing break** check box.
Figure 14.8. Typing Break Properties

To increase or decrease the amount of time you want to be allowed to type before the break is enforced, click the up or down button next to the **Work interval lasts** label respectively. You can do the same with the **Break interval lasts** setting to alter the length of the break itself. Finally, select the **Allow postponing of breaks** check box if you want to be able to delay the break in case you need to finish the work. The changes take effect immediately.
Next time you reach the time limit, you will be presented with a screen advising you to take a break, and a clock displaying the remaining time. If you enabled it, the **Postpone Break** button will be located at the bottom right corner of the screen.
Users and Groups

The control of users and groups is a core element of Red Hat Enterprise Linux system administration.

Users can be either people (meaning accounts tied to physical users) or accounts which exist for specific applications to use.

Groups are logical expressions of organization, tying users together for a common purpose. Users within a group can read, write, or execute files owned by that group.

Each user is associated with a unique numerical identification number called a userid (UID); likewise, each group is associated with a groupid (GID).

A user who creates a file is also the owner and group owner of that file. The file is assigned separate read, write, and execute permissions for the owner, the group, and everyone else. The file owner can be changed only by the root user, and access permissions can be changed by both the root user and file owner.

Red Hat Enterprise Linux also supports access control lists (ACLs) for files and directories which allow permissions for specific users outside of the owner to be set. For more information about ACLs, refer to chapter ACLS.

15.1. User and Group Configuration

The User Manager allows you to view, modify, add, and delete local users and groups.

You can start the User Manager by clicking System → Administration → Users and Groups. Alternatively, you can enter system-config-users at the shell prompt to open the User Manager. Viewing and modifying user and group information requires superuser privileges. If you are not the superuser when you open the User Manager, it will prompt you for the superuser password.

To view a list of local users on the system, click the Users tab. To view a list of local groups on the system, click the Groups tab.

To find a specific user or group, type the first few letters of the name in the Search filter field. Press Enter or click the Apply filter button. The filtered list is displayed.

To sort the users, click on the column User Name and for groups click on Group Name. The users or groups are sorted according to the value of that column.

Red Hat Enterprise Linux reserves user IDs below 500 for system users. By default, the User Manager does not display system users. To view all users, including the system users, go to Edit > Preferences and uncheck Hide system users and groups from the dialog box.
15.1.1. Adding a New User

To add a new user, click the Add User button. A window as shown in Figure 15.2, "Creating a new user" appears. Type the username and full name for the new user in the appropriate fields. Type the user's password in the Password and Confirm Password fields. The password must be at least six characters.

Tip

It is advisable to use a much longer password, as this makes it more difficult for an intruder to guess it and access the account without permission. It is also recommended that the password not be based on a dictionary term; use a combination of letters, numbers and special characters.

Select a login shell from the pulldown list. If you are not sure which shell to select, accept the default value of /bin/bash. The default home directory is /home/<username>/. You can change the home directory that is created for the user, or you can choose not to create the home directory by unselecting Create home directory.

If you select to create the home directory, default configuration files are copied from the /etc/skel/ directory into the new home directory.

Red Hat Enterprise Linux uses a user private group (UPG) scheme. The UPG scheme does not add or change anything in the standard UNIX way of handling groups; it offers a new convention. Whenever you create a new user, by default, a unique group with the same name as the user is created. If you do not want to create this group, unselect Create a private group for the user.

To specify a user ID for the user, select Specify user ID manually. If the option is not selected, the next available user ID above 500 is assigned to the new user. Because Red Hat Enterprise Linux reserves user IDs below 500 for system users, it is not advisable to manually assign user IDs 1-499.

Click OK to create the user.
Adding a New User

To configure more advanced user properties, such as password expiration, modify the user's properties after adding the user.

**Modifying User Properties**

To view the properties of an existing user, click on the **Users** tab, select the user from the user list, and click **Properties** from the menu (or choose **File > Properties** from the pulldown menu). A window similar to Figure 15.3, "User Properties" appears.
Chapter 15. Users and Groups

Figure 15.3. User Properties

The User Properties window is divided into multiple tabbed pages:

- **User Data** — Shows the basic user information configured when you added the user. Use this tab to change the user's full name, password, home directory, or login shell.

- **Account Info** — Select Enable account expiration if you want the account to expire on a certain date. Enter the date in the provided fields. Select Local password is locked to lock the user account and prevent the user from logging into the system.

- **Password Info** — Displays the date that the user's password last changed. To force the user to change passwords after a certain number of days, select Enable password expiration and enter a desired value in the Days before change required field. The number of days before the user's password expires, the number of days before the user is warned to change passwords, and days before the account becomes inactive can also be changed.

- **Groups** — Allows you to view and configure the Primary Group of the user, as well as other groups that you want the user to be a member of.

### 15.1.2. Adding a New Group

To add a new user group, select Add Group from the toolbar. A window similar to Figure 15.4, “New Group” appears. Type the name of the new group. To specify a group ID for the new group, select Specify group ID manually and select the GID. Note that Red Hat Enterprise Linux also reserves group IDs lower than 500 for system groups.

Click OK to create the group. The new group appears in the group list.
15.1.3. Modifying Group Properties
To view the properties of an existing group, select the group from the group list and click Properties from the menu (or choose File > Properties from the pulldown menu). A window similar to Figure 15.5, “Group Properties” appears.

![Figure 15.5. Group Properties](image)

The Group Users tab displays which users are members of the group. Use this tab to add or remove users from the group. Click OK to save your changes.

15.2. User and Group Management Tools
Managing users and groups can be tiresome; this is why Red Hat Enterprise Linux provides tools and conventions to make this task easier to manage.

The easiest way to manage users and groups is through the graphical application, User Manager (system-config-users). For more information on User Manager, refer to Section 15.1, “User and Group Configuration”.

The following command line tools can also be used to manage users and groups:

- **useradd**, **usermod**, and **userdel** — Industry-standard methods of adding, deleting and modifying user accounts
- **groupadd**, **groupmod**, and **groupdel** — Industry-standard methods of adding, deleting, and modifying user groups
- **gpasswd** — Industry-standard method of administering the /etc/group file
- **pwck**, **grpck** — Tools used for the verification of the password, group, and associated shadow files
- **pwconv**, **pwunconv** — Tools used for the conversion of passwords to shadow passwords and back to standard passwords

15.2.1. Command Line Configuration
If you prefer command line tools or do not have the X Window System installed, use following to configure users and groups.
Adding a User

To add a user to the system:

1. Issue the `useradd` command to create a locked user account:

   ```bash
   useradd <username>
   ```

2. Unlock the account by issuing the `passwd` command to assign a password and set password aging guidelines:

   ```bash
   passwd <username>
   ```

Command line options for `useradd` are detailed in Table 15.1, "useradd Command Line Options".

### Table 15.1. useradd Command Line Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-c 'comment'</code></td>
<td><code>&lt;comment&gt;</code> can be replaced with any string. This option is generally used to specify the full name of a user.</td>
</tr>
<tr>
<td><code>-d &lt;home-dir&gt;</code></td>
<td>Home directory to be used instead of default <code>/home/&lt;username&gt;/</code></td>
</tr>
<tr>
<td><code>-e &lt;date&gt;</code></td>
<td>Date for the account to be disabled in the format YYYY-MM-DD</td>
</tr>
<tr>
<td><code>-f &lt;days&gt;</code></td>
<td>Number of days after the password expires until the account is disabled. If 0 is specified, the account is disabled immediately after the password expires. If -1 is specified, the account is not be disabled after the password expires.</td>
</tr>
<tr>
<td><code>-g &lt;group-name&gt;</code></td>
<td>Group name or group number for the user's default group. The group must exist prior to being specified here.</td>
</tr>
<tr>
<td><code>-G &lt;group-list&gt;</code></td>
<td>List of additional (other than default) group names or group numbers, separated by commas, of which the user is a member. The groups must exist prior to being specified here.</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Create the home directory if it does not exist.</td>
</tr>
<tr>
<td><code>-M</code></td>
<td>Do not create the home directory.</td>
</tr>
<tr>
<td><code>-N</code></td>
<td>Do not create a user private group for the user.</td>
</tr>
<tr>
<td><code>-p &lt;password&gt;</code></td>
<td>The password encrypted with <code>crypt</code></td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Create a system account with a UID less than 500 and without a home directory</td>
</tr>
<tr>
<td><code>-s</code></td>
<td>User's login shell, which defaults to <code>/bin/bash</code></td>
</tr>
<tr>
<td><code>-u &lt;uid&gt;</code></td>
<td>User ID for the user, which must be unique and greater than 499</td>
</tr>
</tbody>
</table>

Adding a Group

To add a group to the system, use the command `groupadd`:

```bash
groupadd <group-name>
```

Command line options for `groupadd` are detailed in Table 15.2, "groupadd Command Line Options".
Table 15.2. groupadd Command Line Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>When used with -g &lt;gid&gt; and &lt;gid&gt; already exists, groupadd will choose another unique &lt;gid&gt; for the group.</td>
</tr>
<tr>
<td>-g &lt;gid&gt;</td>
<td>Group ID for the group, which must be unique and greater than 499</td>
</tr>
<tr>
<td>-K, --key KEY=VALUE</td>
<td>override /etc/login.defs defaults</td>
</tr>
<tr>
<td>-o, --non-unique</td>
<td>allow to create groups with duplicate</td>
</tr>
<tr>
<td>-p, --password PASSWORD</td>
<td>use this encrypted password for the new group</td>
</tr>
<tr>
<td>-r</td>
<td>Create a system group with a GID less than 500</td>
</tr>
</tbody>
</table>

Password Aging

For security reasons, it is advisable to require users to change their passwords periodically. This can be done when adding or editing a user on the Password Info tab of the User Manager.

To configure password expiration for a user from a shell prompt, use the chage command with an option from Table 15.3, “chage Command Line Options”, followed by the username.

Important

Shadow passwords must be enabled to use the chage command. For more information, see Section 15.6, “Shadow Passwords”.

Table 15.3. chage Command Line Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d &lt;days&gt;</td>
<td>Specifies the number of days since January 1, 1970 the password was changed</td>
</tr>
<tr>
<td>-E &lt;date&gt;</td>
<td>Specifies the date on which the account is locked, in the format YYYY-MM-DD. Instead of the date, the number of days since January 1, 1970 can also be used.</td>
</tr>
<tr>
<td>-I &lt;days&gt;</td>
<td>Specifies the number of inactive days after the password expiration before locking the account. If the value is 0, the account is not locked after the password expires.</td>
</tr>
<tr>
<td>-l</td>
<td>Lists current account aging settings.</td>
</tr>
<tr>
<td>-m &lt;days&gt;</td>
<td>Specify the minimum number of days after which the user must change passwords. If the value is 0, the password does not expire.</td>
</tr>
<tr>
<td>-M &lt;days&gt;</td>
<td>Specify the maximum number of days for which the password is valid. When the number of days specified by this option plus the number of days specified with the -d option is less than the current day, the user must change passwords before using the account.</td>
</tr>
<tr>
<td>-W &lt;days&gt;</td>
<td>Specifies the number of days before the password expiration date to warn the user.</td>
</tr>
</tbody>
</table>
Chapter 15. Users and Groups

Tip

If the `chage` command is followed directly by a username (with no options), it displays the current password aging values and allows them to be changed interactively.

You can configure a password to expire the first time a user logs in. This forces users to change passwords immediately.

1. **Set up an initial password** — There are two common approaches to this step. The administrator can assign a default password or assign a null password.

To assign a default password, use the following steps:

- Start the command line Python interpreter with the `python` command. It displays the following:

  ```
  Python 2.4.3 (#1, Jul 21 2006, 08:46:09)
  [GCC 4.1.1 20060718 (Application Stack 4.1.1-9)] on linux2
  Type "help", "copyright", "credits" or "license" for more information.
  >>>
  ```

- At the prompt, type the following commands. Replace `<password>` with the password to encrypt and `<salt>` with a random combination of at least 2 of the following: any alphanumeric character, the slash (/) character or a dot (.):

  ```
  import crypt; print crypt.crypt("<password>","<salt>")
  ```

  The output is the encrypted password, similar to `'12CsGd8FRcMSM'`.

- Press Ctrl-D to exit the Python interpreter.

- At the shell, enter the following command (replacing `<encrypted-password>` with the encrypted output of the Python interpreter):

  ```
  usermod -p "<encrypted-password>" <username>
  ```

Alternatively, you can assign a null password instead of an initial password. To do this, use the following command:

```
usermod -p "" username
```

Caution

Using a null password, while convenient, is a highly unsecure practice, as any third party can log in first and access the system using the unsecure username. Always make sure that the user is ready to log in before unlocking an account with a null password.

2. **Force immediate password expiration** — Type the following command:
chage -d 0 username

This command sets the value for the date the password was last changed to the epoch (January 1, 1970). This value forces immediate password expiration no matter what password aging policy, if any, is in place.

Upon the initial log in, the user is now prompted for a new password.

15.2.2. Explaining the Process
The following steps illustrate what happens if the command `useradd juan` is issued on a system that has shadow passwords enabled:

1. A new line for `juan` is created in `/etc/passwd`.

```
juan:x:501:501::/home/juan:/bin/bash
```

The line has the following characteristics:

- It begins with the username `juan`.
- There is an x for the password field indicating that the system is using shadow passwords.
- A UID greater than 499 is created. Under Red Hat Enterprise Linux, UIDs and GIDs below 500 are reserved for system use. These should not be assigned to users.
- A GID greater than 499 is created.
- The optional GECOS information is left blank.
- The home directory for `juan` is set to `/home/juan/`.
- The default shell is set to `/bin/bash`.

2. A new line for `juan` is created in `/etc/shadow`.

```
juan:!!:14798:0:99999:7:::
```

The line has the following characteristics:

- It begins with the username `juan`.
- Two exclamation points (!!) appear in the password field of the `/etc/shadow` file, which locks the account.
- The password is set to never expire.

3. A new line for a group named `juan` is created in `/etc/group`.
A group with the same name as a user is called a user private group. For more information on user private groups, refer to Section 15.1.1, “Adding a New User”.

The line created in /etc/group has the following characteristics:

- It begins with the group name juan.
- An x appears in the password field indicating that the system is using shadow group passwords.
- The GID matches the one listed for user juan in /etc/passwd.

4. A new line for a group named juan is created in /etc/gshadow.

    juan:!::

The line has the following characteristics:

- It begins with the group name juan.
- An exclamation point (!) appears in the password field of the /etc/gshadow file, which locks the group.
- All other fields are blank.

5. A directory for user juan is created in the /home/ directory.

    ls -l /home
    drwx------. 4 juan juan 4096 Jul 9 14:55 juan

This directory is owned by user juan and group juan. It has read, write, and execute privileges only for the user juan. All other permissions are denied.

6. The files within the /etc/skel/ directory (which contain default user settings) are copied into the new /home/juan/ directory.

At this point, a locked account called juan exists on the system. To activate it, the administrator must next assign a password to the account using the passwd command and, optionally, set password aging guidelines.

15.3. Standard Users

Table 15.4, “Standard Users” lists the standard users configured in the /etc/passwd file by an Everything installation. The groupid (GID) in this table is the primary group for the user. See Section 15.4, “Standard Groups” for a listing of standard groups.

## 15.5. User Private Groups

Red Hat Enterprise Linux uses a *user private group* (UPG) scheme, which makes UNIX groups easier to manage.

A UPG is created whenever a new user is added to the system. A UPG has the same name as the user for which it was created and that user is the only member of the UPG.

UPGs make it safe to set default permissions for a newly created file or directory, allowing both the user and the *group of that user* to make modifications to the file or directory.

The setting which determines what permissions are applied to a newly created file or directory is called a *umask* and is configured in the `/etc/bashrc` file. Traditionally on UNIX systems, the *umask* is set to 022, which allows only the user who created the file or directory to make modifications. Under this scheme, all other users, *including members of the creator's group*, are not allowed to make any modifications. However, under the UPG scheme, this "group protection" is not necessary since every user has their own private group.

### 15.5.1. Group Directories

System administrators usually like to create a group for each major project and assign people to the group when they need to access that project's files. With this traditional scheme, file managing is difficult; when someone creates a file, it is associated with the primary group to which they belong. When a single person works on multiple projects, it becomes difficult to associate the right files with the right group. However, with the UPG scheme, groups are automatically assigned to files created within a directory with the *setgid* bit set. The setgid bit makes managing group projects that share a common directory very simple because any files a user creates within the directory are owned by the group which owns the directory.
Chapter 15. Users and Groups

For example, a group of people need to work on files in the /usr/share/emacs/site-lisp/ directory. Some people are trusted to modify the directory, but not everyone. First create an emacs group, as in the following command:

```
/usr/sbin/groupadd emacs
```

To associate the contents of the directory with the emacs group, type:

```
chown -R root.emacs /usr/share/emacs/site-lisp
```

Now, it is possible to add the right users to the group with the `gpasswd` command:

```
/usr/bin/gpasswd -a <username> emacs
```

To allow users to create files within the directory, use the following command:

```
chmod 775 /usr/share/emacs/site-lisp
```

When a user creates a new file, it is assigned the group of the user’s default private group. Next, set the setgid bit, which assigns everything created in the directory the same group permission as the directory itself (emacs). Use the following command:

```
chmod 2775 /usr/share/emacs/site-lisp
```

At this point, because the default umask of each user is 002, all members of the emacs group can create and edit files in the /usr/share/emacs/site-lisp/ directory without the administrator having to change file permissions every time users write new files.

The command `ls -l /usr/share/emacs/` displays the current settings:

```
total 4
drwxrwsr-x. 2 root emacs 4096 May 18 15:41 site-lisp
```

15.6. Shadow Passwords

In multiuser environments it is very important to use shadow passwords (provided by the shadow-utils package). Doing so enhances the security of system authentication files. For this reason, the installation program enables shadow passwords by default.

The following list shows the advantages shadow passwords have over the traditional way of storing passwords on UNIX-based systems:

- Improves system security by moving encrypted password hashes from the world-readable /etc/passwd file to /etc/shadow, which is readable only by the root user.
- Stores information about password aging.
- Allows the /etc/login.defs file to enforce security policies.
Most utilities provided by the `shadow-utils` package work properly whether or not shadow passwords are enabled. However, since password aging information is stored exclusively in the `/etc/shadow` file, any commands which create or modify password aging information do not work.

The following is a list of commands which do not work without first enabling shadow passwords:

- `chage`
- `gpasswd`
- `/usr/sbin/usermod -e` or `-f` options
- `/usr/sbin/useradd -e` or `-f` options

## 15.7. Additional Resources

For more information about users and groups, and tools to manage them, refer to the following resources.

### 15.7.1. Installed Documentation

- Related man pages — There are a number of man pages for the various applications and configuration files involved with managing users and groups. Some of the more important man pages have been listed here:

  **User and Group Administrative Applications**
  - `man chage` — A command to modify password aging policies and account expiration.
  - `man gpasswd` — A command to administer the `/etc/group` file.
  - `man groupadd` — A command to add groups.
  - `man grpck` — A command to verify the `/etc/group` file.
  - `man groupdel` — A command to remove groups.
  - `man groupmod` — A command to modify group membership.
  - `man pwck` — A command to verify the `/etc/passwd` and `/etc/shadow` files.
  - `man pwconv` — A tool to convert standard passwords to shadow passwords.
  - `man pwunconv` — A tool to convert shadow passwords to standard passwords.
  - `man useradd` — A command to add users.
  - `man userdel` — A command to remove users.
  - `man usermod` — A command to modify users.

  **Configuration Files**
  - `man 5 group` — The file containing group information for the system.
  - `man 5 passwd` — The file containing user information for the system.
  - `man 5 shadow` — The file containing passwords and account expiration information for the system.
Automated Tasks

In Linux, tasks, which are also known as jobs, can be configured to run automatically within a specified period of time, on a specified date, or when the system load average is below a specified number. Red Hat Enterprise Linux is pre-configured to run important system tasks to keep the system updated. For example, the slocate database used by the locate command is updated daily. A system administrator can use automated tasks to perform periodic backups, monitor the system, run custom scripts, and more.

Red Hat Enterprise Linux comes with several automated tasks utilities: cron, at, and batch.

16.1. Cron and Anacron

Both, Cron and Anacron, are daemons that can be used to schedule the execution of recurring tasks according to a combination of the time, day of the month, month, day of the week, and week.

Cron assumes that the system is on continuously. If the system is not on when a job is scheduled, it is not executed. Cron allows jobs to be run as often as every minute. Anacron does not assume the system is always on, remembers every scheduled job, and executes it the next time the system is up. However, Anacron can only run a job once a day. To schedule recurring jobs, refer to Section 16.1.2, “Configuring Anacron Jobs” or Section 16.1.3, “Configuring Cron Jobs”. To schedule one-time jobs, refer to Section 16.2, “At and Batch”.

To use the cron service, the cronie RPM package must be installed and the crond service must be running. anacron is a sub-package of cronie. To determine if these packages are installed, use the rpm -q cronie cronie-anacron command.

16.1.1. Starting and Stopping the Service

To determine if the service is running, use the command /sbin/service crond status. To start the cron service, use the command /sbin/service crond start. To stop the service, use the command /sbin/service crond stop. It is recommended that you start the service at boot time. Refer to Chapter 7, Controlling Access to Services for details on starting the cron service automatically at boot time.

16.1.2. Configuring Anacron Jobs

The main configuration file to schedule jobs is /etc/anacrontab (only root is allowed to modify this file), which contains the following lines:

```
SHELL=/bin/sh
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root
# the maximal random delay added to the base delay of the jobs
RANDOM_DELAY=45
# the jobs will be started during the following hours only
START_HOURS_RANGE=3-22

#period in days delay in minutes job-identifier command
1  5 cron.daily nice run-parts /etc/cron.daily
7  25 cron.weekly nice run-parts /etc/cron.weekly
@monthly 45 cron.monthly nice run-parts /etc/cron.monthly
```

The first three lines are variables used to configure the environment in which the anacron tasks are run. The SHELL variable tells the system which shell environment to use (in this example the bash
Chapter 16. Automated Tasks

shell). The PATH variable defines the path used to execute commands. The output of the anacron jobs are emailed to the username defined with the MAILTO variable. If the MAILTO variable is not defined, (i.e. is empty, MAILTO=), email is not sent.

The next two lines are variables that modify the time for each scheduled job. The RANDOM_DELAY variable denotes the maximum number of minutes that will be added to the delay in minutes variable which is specified for each job. The minimum delay value is set, by default, to 6 minutes. A RANDOM_DELAY set to 12 would therefore add, randomly, between 6 and 12 minutes to the delay in minutes for each job in that particular anacrontab. RANDOM_DELAY can also be set to a value below 6, or even 0. When set to 0, no random delay is added. This proves to be useful when, for example, more computers that share one network connection need to download the same data every day. The START_HOURS_RANGE variable defines an interval (in hours) when scheduled jobs can be run. In case this time interval is missed, for example, due to a power down, then scheduled jobs are not executed that day.

The rest of the lines in the /etc/anacrontab file represent scheduled jobs and have the following format:

<table>
<thead>
<tr>
<th>period in days</th>
<th>delay in minutes</th>
<th>job-identifier</th>
<th>command</th>
</tr>
</thead>
</table>

- **period in days** — specifies the frequency of execution of a job in days. This variable can be represented by an integer or a macro (@daily, @weekly, @monthly), where @daily denotes the same value as the integer 1, @weekly the same as 7, and @monthly specifies that the job is run once a month, independent on the length of the month.

- **delay in minutes** — specifies the number of minutes anacron waits, if necessary, before executing a job. This variable is represented by an integer where 0 means no delay.

- **job-identifier** — specifies a unique name of a job which is used in the log files.

- **command** — specifies the command to execute. The command can either be a command such as ls /proc >> /tmp/proc or a command to execute a custom script.

Any lines that begin with a hash sign (#) are comments and are not processed.

### 16.1.2.1. Examples of Anacron Jobs

The following example shows a simple /etc/anacrontab file:

```bash
SHELL=/bin/sh
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root

# the maximal random delay added to the base delay of the jobs
RANDOM_DELAY=30

# the jobs will be started during the following hours only
START_HOURS_RANGE=16-20

#period in days  delay in minutes  job-identifier    command
1         20    dailyjob      nice run-parts /etc/cron.daily
7         25    weeklyjob     /etc/weeklyjob.bash
@monthly  45    monthlyjob    ls /proc >> /tmp/proc
```

All jobs defined in this anacrontab file are randomly delayed by 6-30 minutes and can be executed between 16:00 and 20:00. Thus, the first defined job will run anywhere between 16:26 and 16:50 every day. The command specified for this job will execute all present programs in the /etc/cron.daily
directory (using the `run-parts` script which takes a directory as a command-line argument and sequentially executes every program within that directory). The second specified job will be executed once a week and will execute the `weeklyjob.bash` script in the `/etc` directory. The third job is executed once a month and runs a command to write the contents of the `/proc` to the `/tmp/proc` file (e.g. `ls /proc >> /tmp/proc`).

16.1.2.1.1. Disabling Anacron

In case your system is continuously on and you do not require anacron to run your scheduled jobs, you may uninstall the `cronie-anacron` package. Thus, you will be able to define jobs using crontabs only.

16.1.3. Configuring Cron Jobs

The configuration file to configure cron jobs, `/etc/crontab` (only root is allowed to modify this file), contains the following lines:

```
SHELL=/bin/bash
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root
HOME=/
# For details see man 4 crontabs
# Example of job definition:
# .---------------- minute (0 - 59)
# | .------------- hour (0 - 23)
# | | .---------- day of month (1 - 31)
# | | | .------- month (1 - 12) OR jan,feb,mar,apr ...
# | | | | .---- day of week (0 - 6) (Sunday=0 or 7) OR sun,mon,tue,wed,thu,fri,sat
# | | | | |
# * * * * * user command to be executed
```

The first three lines contain the same variables as an `anacrontab` file, SHELL, PATH and MAILTO. For more information about these variables, refer to Section 16.1.2, "Configuring Anacron Jobs". The fourth line contains the HOME variable. The HOME variable can be used to set the home directory to use when executing commands or scripts.

The rest of the lines in the `/etc/crontab` file represent scheduled jobs and have the following format:

```
minute  hour  day  month  day of week  user  command
```

- **minute** — any integer from 0 to 59
- **hour** — any integer from 0 to 23
- **day** — any integer from 1 to 31 (must be a valid day if a month is specified)
- **month** — any integer from 1 to 12 (or the short name of the month such as jan or feb)
- **day of week** — any integer from 0 to 7, where 0 or 7 represents Sunday (or the short name of the week such as sun or mon)
- **user** — specifies the user under which the jobs are run
- **command** — the command to execute (the command can either be a command such as `ls /proc >> /tmp/proc` or the command to execute a custom script)
Chapter 16. Automated Tasks

For any of the above values, an asterisk (*) can be used to specify all valid values. For example, an asterisk for the month value means execute the command every month within the constraints of the other values.

A hyphen (-) between integers specifies a range of integers. For example, 1-4 means the integers 1, 2, 3, and 4.

A list of values separated by commas (,) specifies a list. For example, 3, 4, 6, 8 indicates those four specific integers.

The forward slash (/) can be used to specify step values. The value of an integer can be skipped within a range by following the range with /<integer>. For example, 9-59/2 can be used to define every other minute in the minute field. Step values can also be used with an asterisk. For instance, the value */3 can be used in the month field to run the task every third month.

Any lines that begin with a hash sign (#) are comments and are not processed.

Users other than root can configure cron tasks by using the `crontab` utility. All user-defined crontabs are stored in the `/var/spool/cron/` directory and are executed using the usernames of the users that created them. To create a crontab as a user, login as that user and type the command `crontab -e` to edit the user's crontab using the editor specified by the `VISUAL` or `EDITOR` environment variable. The file uses the same format as `/etc/crontab`. When the changes to the crontab are saved, the crontab is stored according to username and written to the file `/var/spool/cron/username`. To list the contents of your own personal crontab file, use the `crontab -l` command.

**Note**

When using the `crontab` utility, there is no need to specify a user when defining a job.

The `/etc/cron.d/` directory contains files that have the same syntax as the `/etc/crontab` file. Only root is allowed to create and modify files in this directory.

**Note**

The cron daemon checks the `/etc/anacrontab` file, the `/etc/crontab` file, the `/etc/cron.d/` directory, and the `/var/spool/cron/` directory every minute for any changes. If any changes are found, they are loaded into memory. Thus, the daemon does not need to be restarted if an anacrontab or a crontab file is changed.

### 16.1.4. Controlling Access to Cron

The `/etc/cron.allow` and `/etc/cron.deny` files are used to restrict access to cron. The format of both access control files is one username on each line. Whitespace is not permitted in either file. The cron daemon (`crond`) does not have to be restarted if the access control files are modified. The access control files are checked each time a user tries to add or delete a cron job.

The root user can always use cron, regardless of the usernames listed in the access control files.

If the file `cron.allow` exists, only users listed in it are allowed to use cron, and the `cron.deny` file is ignored.

If `cron.allow` does not exist, users listed in `cron.deny` are not allowed to use cron.
Access can also be controlled through Pluggable Authentication Modules (PAM). These settings are stored in `/etc/security/access.conf`. For example, adding the following line in this file forbids creating crontabs for all users except the root user:

```
::ALL EXCEPT root :cron
```

The forbidden jobs are logged in an appropriate log file or, when using "crontab -e", returned to the standard output. For more information, refer to `access.conf.5` (i.e. `man 5 access.conf`).

### 16.1.5. Black/White Listing of Cron Jobs

Black/White listing of jobs is used to omit parts of the defined jobs that do not need to be executed. When calling the `run-parts` script on a cron folder, such as `/etc/cron.daily`, we can define which of the programs in this folder will not be executed by `run-parts`.

To define a black list, create a `jobs.deny` file in the folder that `run-parts` will be executing from. For example, if we need to omit a particular program from `/etc/cron.daily`, then, a file `/etc/cron.daily/jobs.deny` has to be created. In this file, specify the names of the omitted programs from the same directory. These will not be executed when a command, such as `run-parts /etc/cron.daily`, is executed by a specific job.

To define a white list, create a `jobs.allow` file.

The principles of `jobs.deny` and `jobs.allow` are the same as those of `cron.deny` and `cron.allow` described in section [Section 16.1.4, “Controlling Access to Cron”](#).

### 16.2. At and Batch

While cron is used to schedule recurring tasks, the `at` command is used to schedule a one-time task at a specific time and the `batch` command is used to schedule a one-time task to be executed when the systems load average drops below 0.8.

To use `at` or `batch`, the `at` RPM package must be installed, and the `atd` service must be running. To determine if the package is installed, use the `rpm -q at` command. To determine if the service is running, use the command `/sbin/service atd status`.

### 16.2.1. Configuring At Jobs

To schedule a one-time job at a specific time, type the command `at time`, where `time` is the time to execute the command.

The argument `time` can be one of the following:

- **HH:MM format** — For example, 04:00 specifies 4:00 a.m. If the time is already past, it is executed at the specified time the next day.
- **midnight** — Specifies 12:00 a.m.
- **noon** — Specifies 12:00 p.m.
- **teatime** — Specifies 4:00 p.m.
- **month-name day year format** — For example, January 15 2002 specifies the 15th day of January in the year 2002. The year is optional.
Chapter 16. Automated Tasks

• MMDDYY, MM/DD/YY, or MM.DD.YY formats — For example, 011502 for the 15th day of January in the year 2002.

• now + time — time is in minutes, hours, days, or weeks. For example, now + 5 days specifies that the command should be executed at the same time five days from now.

The time must be specified first, followed by the optional date. For more information about the time format, read the /usr/share/doc/at-<version>/timespec text file.

After typing the `at` command with the time argument, the `at>` prompt is displayed. Type the command to execute, press Enter, and press Ctrl+D. Multiple commands can be specified by typing each command followed by the Enter key. After typing all the commands, press Enter to go to a blank line and press Ctrl+D. Alternatively, a shell script can be entered at the prompt, pressing Enter after each line in the script, and pressing Ctrl+D on a blank line to exit. If a script is entered, the shell used is the shell set in the user's SHELL environment, the user's login shell, or /bin/sh (whichever is found first).

If the set of commands or script tries to display information to standard output, the output is emailed to the user.

Use the command `atq` to view pending jobs. Refer to Section 16.2.3, “Viewing Pending Jobs” for more information.

Usage of the `at` command can be restricted. For more information, refer to Section 16.2.5, “Controlling Access to At and Batch” for details.

16.2.2. Configuring Batch Jobs

To execute a one-time task when the load average is below 0.8, use the `batch` command.

After typing the `batch` command, the `at>` prompt is displayed. Type the command to execute, press Enter, and press Ctrl+D. Multiple commands can be specified by typing each command followed by the Enter key. After typing all the commands, press Enter to go to a blank line and press Ctrl+D. Alternatively, a shell script can be entered at the prompt, pressing Enter after each line in the script, and pressing Ctrl+D on a blank line to exit. If a script is entered, the shell used is the shell set in the user's SHELL environment, the user's login shell, or /bin/sh (whichever is found first). As soon as the load average is below 0.8, the set of commands or script is executed.

If the set of commands or script tries to display information to standard out, the output is emailed to the user.

Use the command `atq` to view pending jobs. Refer to Section 16.2.3, “Viewing Pending Jobs” for more information.

Usage of the `batch` command can be restricted. For more information, refer to Section 16.2.5, “Controlling Access to At and Batch” for details.

16.2.3. Viewing Pending Jobs

To view pending `at` and `batch` jobs, use the `atq` command. The `atq` command displays a list of pending jobs, with each job on a line. Each line follows the job number, date, hour, job class, and username format. Users can only view their own jobs. If the root user executes the `atq` command, all jobs for all users are displayed.

16.2.4. Additional Command Line Options

Additional command line options for `at` and `batch` include:
Table 16.1. **at** and **batch** Command Line Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>Read the commands or shell script from a file instead of specifying them at the prompt.</td>
</tr>
<tr>
<td>-m</td>
<td>Send email to the user when the job has been completed.</td>
</tr>
<tr>
<td>-v</td>
<td>Display the time that the job is executed.</td>
</tr>
</tbody>
</table>

16.2.5. Controlling Access to At and Batch

The `/etc/at.allow` and `/etc/at.deny` files can be used to restrict access to the `at` and `batch` commands. The format of both access control files is one username on each line. Whitespace is not permitted in either file. The `at` daemon (`atd`) does not have to be restarted if the access control files are modified. The access control files are read each time a user tries to execute the `at` or `batch` commands.

The root user can always execute `at` and `batch` commands, regardless of the access control files.

If the file `at.allow` exists, only users listed in it are allowed to use `at` or `batch`, and the `at.deny` file is ignored.

If `at.allow` does not exist, users listed in `at.deny` are not allowed to use `at` or `batch`.

16.2.6. Starting and Stopping the Service

To start the `at` service, use the command `/sbin/service atd start`. To stop the service, use the command `/sbin/service atd stop`. It is recommended that you start the service at boot time. Refer to Chapter 7, Controlling Access to Services for details on starting the cron service automatically at boot time.

16.3. Additional Resources

To learn more about configuring automated tasks, refer to the following resources.

16.3.1. Installed Documentation

- `cron` man page — contains an overview of cron.
- `crontab` man pages in sections 1 and 5 — The man page in section 1 contains an overview of the `crontab` file. The man page in section 5 contains the format for the file and some example entries.
- `anacron` man page — contains an overview of anacron.
- `anacrontab` man page — contains an overview of the `anacrontab` file.
- `/usr/share/doc/at-<version>/timespec` contains more detailed information about the times that can be specified for cron jobs.
- `at` man page — description of `at` and `batch` and their command line options.
Log Files

Log files are files that contain messages about the system, including the kernel, services, and applications running on it. There are different log files for different information. For example, there is a default system log file, a log file just for security messages, and a log file for cron tasks.

Log files can be very useful when trying to troubleshoot a problem with the system such as trying to load a kernel driver or when looking for unauthorized log in attempts to the system. This chapter discusses where to find log files, how to view log files, and what to look for in log files.

Some log files are controlled by a daemon called `rsyslogd`. A list of log messages maintained by `rsyslogd` can be found in the `/etc/rsyslog.conf` configuration file.

`rsyslog` replaced `syslogd` as the default program for forwarding syslog messages over the network. `rsyslog` uses the basic `syslog` protocol and extends its functionality with enhanced filtering, encryption protected relaying of messages, various configuration options, or support for transportation via the TCP or UDP protocols.

17.1. Configuring rsyslog

The main configuration file for `rsyslog` is `/etc/rsyslog.conf`. It is essentially divided in the following parts:

- Modules
- Global directives
- Rules
- Templates
- Filter conditions
- Output channels

Each of these segments of the `/etc/rsyslog.conf` configuration file is described in the sections below.

Note

In your `/etc/rsyslog.conf` configuration file, any empty lines or any text following a hash sign (#) are comments and are not processed.

17.1.1. Modules

Due to its modular design, `rsyslog` offers a variety of modules which provide dynamic functionality. Note that modules can be written by third parties. Essentially, modules are comprised of various configuration directives that become available when a module is loaded. To load a module, use the following syntax:

```
$ModLoad <MODULE>
```
Chapter 17. Log Files

where `<MODULE>` represents your desired module. For example, if you want to load the **Text File Input Module** (`imfile`) — enables **rsyslog** to convert any standard text files into a syslog messages), specify the following line in your `/etc/rsyslog.conf` configuration file:

```
$ModLoad imfile
```

**rsyslog** offers a number of modules which are split into these main categories:

- **Input Modules** — Input modules gather messages from various sources. The name of an input module always starts with the `im` prefix, such as `imfile`, `imrelp`, etc.

- **Output Modules** — Output modules process messages into different formats or perform various actions on them. The name of an output module always starts with the `om` prefix, such as `omsnmp`, `omrelp`, etc.

- **Filter Modules** — Filter modules provide the ability to filter messages according to specified rules. The name of a filter module always starts with the `fm` prefix.

- **Parser Modules** — Parser modules use the message parsers to parse message content of any received messages. The name of a parser module always starts with the `pm` prefix, such as `pmrfc5424`, `pmrfc3164`, etc.

- **Message Modification Modules** — Message modification modules change the content of an syslog message. The message modification modules only differ in their implementation from the output and filter modules but share the same interface.

- **String Generator Modules** — String generator modules generate strings based on the message content and strongly cooperate with the template feature provided by **rsyslog**. For more information on templates, refer to . The name of a string generator module always starts with the `sm` prefix, such as `smfile`, `smtradfile`, etc.

- **Library Modules** — Library modules provide the ability to load and handle other loadable modules. These modules are loaded automatically by **rsyslog** when needed and cannot be configured by the user.

A comprehensive list of all available modules and their detailed description can be found at [http://www.rsyslog.com/doc/rsyslog_conf_modules.html](http://www.rsyslog.com/doc/rsyslog_conf_modules.html)

**Warning**

Note that when **rsyslog** loads any modules, it provides them with access to some of its functions and data. This poses a possible security threat. To minimize security risks, use trustworthy modules only.

17.1.2. Global Directives

**Global directives** specify configuration options that apply to the **rsyslogd** daemon. All of the global directives must start with a dollar sign (`$`). Only one directive can be specified per line. The following is an example of a global directive that specifies the maximum size of the syslog message queue:

```
```

The default size defined for this directive (10,000 messages) can be overridden by specifying a different value.

A comprehensive list of all available configuration directives and their detailed description can be found in `/usr/share/doc/rsyslog-4.4.2/rsyslog_conf_global.html` or online at [http://www.rsyslog.com/doc/rsyslog_conf_global.html](http://www.rsyslog.com/doc/rsyslog_conf_global.html).

### 17.1.3. Rules

A rule specifies the cooperation of a selector with an action. To define a rule in your `/etc/rsyslog.conf` configuration file, define both, a selector and an action, on one line and separate them with one or more spaces or tabs. For more information on selectors, refer to Section 17.1.3.1, “Selectors” and for information on actions, refer to Section 17.1.3.2, “Actions”.

### 17.1.3.1. Selectors

Selectors filter syslog messages based on two conditions: `facility` and `priority`. The following is an example of a selector:

```
<FACILITY> . <PRIORITY>
```

where:

- `<FACILITY>` specifies the subsystem that produces a specific syslog message. For example, the `mail` subsystem handles all mail related syslog messages. `<FACILITY>` can be represented by one of these keywords: `auth`, `authpriv`, `cron`, `daemon`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, and `local0` through `local7`.

- `<PRIORITY>` specifies a priority of a syslog message. `<PRIORITY>` can be represented by one of these keywords: `debug`, `info`, `notice`, `warning`, `err`, `crit`, `alert`, and `emerg`.

  By preceding any priority with an equal sign (=), you specify that only syslog messages with that priority will be selected. All other priorities will be ignored. Conversely, preceding a priority with an exclamation mark (!) selects all syslog messages but those with the defined priority. By not using either of these two extensions, you specify a selection of syslog messages with the defined priority and higher.

  In addition to the keywords specified above, you may also use an asterisk (*) to define all facilities or priorities (depending on where you place the asterisk, before or after the dot). Specifying the keyword `none` serves for facilities with no given priorities.

  To define multiple facilities and priorities, simply separate them with a comma (,). To define multiple selectors on one line, separate them with a semi-colon (;).

  The following are a few examples of simple selectors:

```
kern.* # Selects all kernel syslog messages with any priority

mail.crit # Selects all mail syslog messages with priority crit and higher.
```
17.1.3.2. Actions
Actions specify what is to be done with the messages filtered out by the defined selector. The following are some of the actions you can define in your rule:

Syslog message placement
The majority of actions specify to which log file a syslog message is saved. This is done by specifying a file path after your already defined selector. The following is a rule comprised of a selector that selects all cron syslog messages and an action that saves them into the /var/log/cron log file:

```
cron.* /var/log/cron
```

Use a dash mark (-) as a prefix of the file path you specified if you want to omit syncing the desired log file after every syslog message is generated.

Your specified file path can be either static or dynamic. Static files are represented by a simple file path as was shown in the example above. Dynamic files are represented by a template and a question mark (?) prefix. For more information on templates, refer to Section 17.1.4, “Templates”.

Sending syslog messages over the network
rsyslog allows you to send and receive syslog messages over the network. This feature allows to administer syslog messages of multiple hosts on one machine. To forward syslog messages to a remote machine, use the following syntax:

```
@[((OPTION>,<MORE OPTIONS>)<HOST>:[<PORT>]
```

where:

- The at sign (@) indicates that the syslog messages are forwarded to a host using the UDP protocol. To use the TCP protocol, use two at signs with no space between them (@@).
- The OPTION and MORE OPTIONS attributes can be replaced with an option such as z<number>. This option enables zlib compression for syslog messages; the NUMBER attribute specifies the level of compression.
- The HOST attribute specifies the host which receives the selected syslog messages.
- The PORT attribute specifies the host machine’s port.

When specifying an IPv6 address as the host, enclose the address in square brackets ([ ]).

The following are some examples of actions that forward syslog messages over the network (note that all actions are preceded with a selector that selects all messages with any priority):
Sending syslog messages to specific users

`rsyslog` can send syslog messages to specific users by simply specifying a username of the user you wish to send the messages to. To specify more than one user, separate each username with a comma (,). To send messages to every user that is currently logged on, use an asterisk (*).

Discarding syslog messages

To discard your selected messages, use the tilde character (~). The following rule discards any cron syslog messages:

```
cron.* ~
```

Note that any action can be followed by a template that formats the message. To specify a template, suffix an action with a semicolon (;) and specify the name of the template.

---

**Caution**

A template must be defined before it is used in an action.

---

For more information on templates, refer to Section 17.1.4, “Templates”.

For more information on various `rsyslog` actions, refer to `/usr/share/doc/rsyslog-4.4.2/rsyslog_conf_actions.html`.

### 17.1.4. Templates

### 17.1.5. Filter Conditions

### 17.1.6. Output Channels

### 17.2. rsyslog Performance

### 17.3. Locating Log Files

Most log files are located in the `/var/log/` directory. Some applications such as `httpd` and `samba` have a directory within `/var/log/` for their log files.

You may notice multiple files in the `/var/log/` directory with numbers after them (e.g.: `cron-20100906`). These numbers represent a timestamp that has been added to a rotated log file. Log files are rotated so their file sizes do not become too large. The `logrotate` package contains a cron task that automatically rotates log files according to the `/etc/logrotate.conf` configuration file and the configuration files in the `/etc/logrotate.d/` directory.

#### 17.3.1. Configuring `logrotate`

The following is a sample `/etc/logrotate.conf` configuration file:
# rotate log files weekly
weekly
# keep 4 weeks worth of backlogs
rotate 4
# uncomment this if you want your log files compressed
compress

All of the lines in the sample configuration file define global options that apply to every log file. In our example, log files are rotated weekly, rotated log files are kept for the duration of 4 weeks, and all rotated log files are compressed by `gzip` into the `.gz` format. Any lines that begin with a hash sign (#) are comments and are not processed.

You may define configuration options for a specific log file and place it under the global options. However, it is advisable to create a separate configuration file for any specific log file in the `/etc/logrotate.d/` directory and define any configuration options there.

The following is an example of a configuration file placed in the `/etc/logrotate.d/` directory:

```bash
/var/log/messages {  
  rotate 5  
  weekly  
  postrotate  
  /usr/bin/killall -HUP syslogd  
  endscript  
}
```

The configuration options in this file are specific for the `/var/log/messages` log file only. The settings specified here override the global settings where possible. Thus the rotated `/var/log/messages` log file will be kept for five weeks instead of four weeks as was defined in the global options.

The following is a list of some of the directives you can specify in your `logrotate` configuration file:

- `weekly` — Specifies the rotation of log files on a weekly basis. Similar directives include:
  - `daily`
  - `monthly`
  - `yearly`
- `compress` — Enables compression of rotated log files. Similar directives include:
  - `nocompress`
  - `compresscmd` — Specifies the command to be used for compressing.
  - `uncompresscmd`
  - `compressext` — Specifies what extension is to be used for compressing.
  - `compressoptions` — Lets you specify any options that may be passed to the used compression program.
  - `delaycompress` — Postpones the compression of log files to the next rotation of log files.
- `rotate <INTEGER>` — Specifies the number of rotations a log file undergoes before it is removed or mailed to a specific address. If the value 0 is specified, old log files are removed instead of rotated.
• mail <ADDRESS> — This option enables mailing of log files that have been rotated as many times as is defined by the rotate directive to the specified address. Similar directives include:
  
  • nomail
  
  • mailfirst — Specifies that the just-rotated log files are to be mailed, instead of the about-to-expire log files.
  
  • maillast — Specifies that the just-rotated log files are to be mailed, instead of the about-to-expire log files. This is the default option when mail is enabled.

For the full list of directives and various configuration options, refer to the logrotate man page (man logrotate).

17.4. Viewing Log Files

Most log files are in plain text format. You can view them with any text editor such as vi or Emacs. Some log files are readable by all users on the system; however, root privileges are required to read most log files.

To view system log files in an interactive, real-time application, use the Log File Viewer.

Note: Installing the gnome-system-log package

In order to use the Log File Viewer, first ensure the gnome-system-log package is installed on your system by running, as root:

```bash
$ yum install gnome-system-log
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

After you have installed the gnome-system-log package, you can open the Log File Viewer by clicking on Applications → System → Log File Viewer, or type the following command at a shell prompt:

```bash
$ gnome-system-log
```

The application only displays log files that exist; thus, the list might differ from the one shown in Figure 17.1, "Log File Viewer".
The Log File Viewer application lets you filter any existing log file. Click on Filters from the menu and select Manage Filters to define or edit your desired filter.

Adding or editing a filter lets you define its parameters as is shown in Figure 17.3, “Log File Viewer - Defining a Filter”.

Figure 17.1. Log File Viewer

Figure 17.2. Log File Viewer - Filters

Figure 17.3. Log File Viewer - Defining a Filter
When defining a filter, you can edit the following parameters:

- **Name** — Specifies the name of the filter.

- **Regular Expression** — Specifies the regular expression that will be applied to the log file and will attempt to match any possible strings of text in it.

- **Effect**
  - **Highlight** — If checked, the found results will be highlighted with the selected color. You may select whether to highlight the background or the foreground of the text.
  - **Hide** — If checked, the found results will be hidden from the log file you are viewing.

When you have at least one filter defined, you may select it from the Filters menu and it will automatically search for the strings you have defined in the filter and highlight/hide every successful match in the log file you are currently viewing.
When you check the **Show matches only** option, only the matched strings will be shown in the log file you are currently viewing.

### 17.5. Adding a Log File

To add a log file you wish to view in the list, select **File → Open**. This will display the **Open Log** window where you can select the directory and filename of the log file you wish to view. *Figure 17.5, “Log File Viewer - Adding a Log File”* illustrates the **Open Log** window.

![Open Log Window](image)

**Figure 17.5. Log File Viewer - Adding a Log File**

Click on the **Open** button to open the file. The file is immediately added to the viewing list where you can select it and view its contents.

![Log File Viewer](image)

**Note**

The **Log File Viewer** also allows you to open log files zipped in the `.gz` format.

### 17.6. Monitoring Log Files

**Log File Viewer** monitors all opened logs by default. If a new line is added to a monitored log file, the log name appears in bold in the log list. If the log file is selected or displayed, the new lines appear in bold at the bottom of the log file. *Figure 17.6, “Log File Viewer - New Log Alert”* illustrates a new alert in the `cron` log file and in the `messages` log file. Clicking on the `cron` log file displays the logs in the file with the new lines in bold.
17.7. Additional Resources
To learn more about `rsyslog`, `logrotate`, and log files in general, refer to the following resources.

17.7.1. Installed Documentation
- `rsyslogd` manual page — Type `man rsyslogd` to learn more about `rsyslogd` and its many options.
- `rsyslog.conf` manual page — Type `man rsyslog.conf` to learn more about the `/etc/rsyslog.conf` configuration file and its many options.
- `/usr/share/doc/rsyslog-<version-number>` — After installing the `rsyslog` package, this directory contains extensive documentation in the HTML format.
- `logrotate` manual page — Type `man logrotate` to learn more about `logrotate` and its many options.

17.7.2. Useful Websites
Chapter 18.

The sysconfig Directory

This chapter outlines some of the files and directories found in the `/etc/sysconfig/` directory, their function, and their contents. The information in this chapter is not intended to be complete, as many of these files have a variety of options that are only used in very specific or rare circumstances.

Note

The actual content of your `/etc/sysconfig/` directory depends on the programs you have installed on your machine. To find the name of the package the configuration file belongs to, type the following at a shell prompt:

```
$ yum provides /etc/sysconfig/filename
```

Refer to Section 1.2.2, “Installing” for more information on how to install new packages in Red Hat Enterprise Linux.

18.1. Files in the `/etc/sysconfig/` Directory

The following sections offer descriptions of files normally found in the `/etc/sysconfig/` directory.

18.1.1. `/etc/sysconfig/arpwatch`

The `/etc/sysconfig/arpwatch` file is used to pass arguments to the `arpwatch` daemon at boot time. By default, it contains the following option:

```
OPTIONS=value
```

Additional options to be passed to the `arpwatch` daemon. For example:

```
OPTIONS=":-u arpwatch -e root -s 'root (Arpwatch)'"
```

18.1.2. `/etc/sysconfig/authconfig`

The `/etc/sysconfig/authconfig` file sets the authorization to be used on the host. By default, it contains the following options:

```
USEMKHOMEDIR=boolean
```

A boolean to enable (yes) or disable (no) creating a home directory for a user on the first login. For example:

```
USEMKHOMEDIR=yes
```

```
USEMKHOMEDIR=no
```

```
USEPAMACCESS=boolean
```

A boolean to enable (yes) or disable (no) the PAM authentication. For example:

```
USEPAMACCESS=yes
```

```
USEPAMACCESS=no
```

```
USESMDAUTH=boolean
```

A boolean to enable (yes) or disable (no) the SSSD authentication. For example:
Chapter 18. The sysconfig Directory

**USESSDAUTH**=no

**USESHADOW**=boolean
A boolean to enable (yes) or disable (no) shadow passwords. For example:

USESHADOW=yes

**USEWINBIND**=boolean
A boolean to enable (yes) or disable (no) using Winbind for user account configuration. For example:

USEWINBIND=no

**USED**=boolean
A boolean to enable (yes) or disable (no) the FAS authentication. For example:

USEDB=no

**USEFPRINTD**=boolean
A boolean to enable (yes) or disable (no) the fingerprint authentication. For example:

USEFPRINTD=yes

**FORCESMARTCARD**=boolean
A boolean to enable (yes) or disable (no) enforcing the smart card authentication. For example:

FORCESMARTCARD=no

**PASSWDALGORITHM**=value
The password algorithm. The value can be bigcrypt, descrypt, md5, sha256, or sha512. For example:

PASSWDALGORITHM=sha512

**USELDAPAUTH**=boolean
A boolean to enable (yes) or disable (no) the LDAP authentication. For example:

USELDAPAUTH=no

**USELOCALAUTHORIZE**=boolean
A boolean to enable (yes) or disable (no) the local authorization for local users. For example:

USELOCALAUTHORIZE=yes

**USECRACKLIB**=boolean
A boolean to enable (yes) or disable (no) using the CrackLib. For example:

USECRACKLIB=yes
USEWINBINDAUTH=boolean
A boolean to enable (yes) or disable (no) the Winbind authentication. For example:

USEWINBINDAUTH=no

USESMAUTH=boolean
A boolean to enable (yes) or disable (no) the smart card authentication. For example:

USESMAUTH=no

USELDAP=boolean
A boolean to enable (yes) or disable (no) using LDAP for user account configuration. For example:

USELDAP=no

USENIS=boolean
A boolean to enable (yes) or disable (no) using NIS for user account configuration. For example:

USENIS=no

USEKERBEROS=boolean
A boolean to enable (yes) or disable (no) the Kerberos authentication. For example:

USEKERBEROS=no

USESNSAUTH=boolean
A boolean to enable (yes) or disable (no) authenticating system accounts with network services. For example:

USESNSAUTH=no

USESMBAUTH=boolean
A boolean to enable (yes) or disable (no) the SMB authentication. For example:

USESMBAUTH=no

USESSSD=boolean
A boolean to enable (yes) or disable (no) using SSSD for obtaining user information. For example:

USESSSD=no

USEHESIOD=boolean
A boolean to enable (yes) or disable (no) using the Hesiod name service. For example:

USEHESIOD=no

Refer to Chapter 8, Authentication Configuration for more information on this topic.
18.1.3. /etc/sysconfig/autofs

The /etc/sysconfig/autofs file defines custom options for the automatic mounting of devices. This file controls the operation of the automount daemons, which automatically mount file systems when you use them and unmount them after a period of inactivity. File systems can include network file systems, CD-ROM drives, diskettes, and other media.

By default, it contains the following options:

**MASTER_MAP_NAME=value**
The default name for the master map. For example:

```
MASTER_MAP_NAME="auto.master"
```

**TIMEOUT=value**
The default mount timeout. For example:

```
TIMEOUT=300
```

**NEGATIVE_TIMEOUT=value**
The default negative timeout for unsuccessful mount attempts. For example:

```
NEGATIVE_TIMEOUT=60
```

**MOUNT_WAIT=value**
The time to wait for a response from `mount`. For example:

```
MOUNT_WAIT=-1
```

**UMOUNT_WAIT=value**
The time to wait for a response from `umount`. For example:

```
UMOUNT_WAIT=12
```

**BROWSE_MODE=boolean**
A boolean to enable (yes) or disable (no) browsing the maps. For example:

```
BROWSE_MODE="no"
```

**MOUNT_NFS_DEFAULT_PROTOCOL=value**
The default protocol to be used by `mount.nfs`. For example:

```
MOUNT_NFS_DEFAULT_PROTOCOL=4
```

**APPEND_OPTIONS=boolean**
A boolean to enable (yes) or disable (no) appending the global options instead of replacing them. For example:

```
APPEND_OPTIONS="yes"
```
LOGGING=\texttt{value}
The default logging level. The \texttt{value} has to be either \texttt{none}, \texttt{verbose}, or \texttt{debug}. For example:

\begin{verbatim}
LOGGING="none"
\end{verbatim}

LDAP\_URI=\texttt{value}
A space-separated list of server URIs in the form of \texttt{protocol://server}. For example:

\begin{verbatim}
LDAP\_URI="ldaps://ldap.example.com/"
\end{verbatim}

LDAP\_TIMEOUT=\texttt{value}
The synchronous API calls timeout. For example:

\begin{verbatim}
LDAP\_TIMEOUT=-1
\end{verbatim}

LDAP\_NETWORK\_TIMEOUT=\texttt{value}
The network response timeout. For example:

\begin{verbatim}
LDAP\_NETWORK\_TIMEOUT=8
\end{verbatim}

SEARCH\_BASE=\texttt{value}
The base Distinguished Name (DN) for the map search. For example:

\begin{verbatim}
SEARCH\_BASE=""
\end{verbatim}

AUTH\_CONF\_FILE=\texttt{value}
The default location of the SASL authentication configuration file. For example:

\begin{verbatim}
AUTH\_CONF\_FILE="/etc/autofs_ldap_auth.conf"
\end{verbatim}

MAP\_HASH\_TABLE\_SIZE=\texttt{value}
The hash table size for the map cache. For example:

\begin{verbatim}
MAP\_HASH\_TABLE\_SIZE=1024
\end{verbatim}

USE\_MISC\_DEVICE=\texttt{boolean}
A boolean to enable (\texttt{yes}) or disable (\texttt{no}) using the autofs miscellaneous device. For example:

\begin{verbatim}
USE\_MISC\_DEVICE="yes"
\end{verbatim}

OPTIONS=\texttt{value}
Additional options to be passed to the LDAP daemon. For example:

\begin{verbatim}
OPTIONS=""
\end{verbatim}
18.1.4. /etc/sysconfig/clock

The /etc/sysconfig/clock file controls the interpretation of values read from the system hardware clock. It is used by the Date/Time Properties tool, and should not be edited by hand. By default, it contains the following option:

ZONE=value
   The time zone file under /usr/share/zoneinfo that /etc/localtime is a copy of. For example:

```
ZONE="Europe/Prague"
```

Refer to Section 13.1, “Date/Time Properties Tool” for more information on the Date/Time Properties tool and its usage.

18.1.5. /etc/sysconfig/dhcpd

The /etc/sysconfig/dhcpd file is used to pass arguments to the dhcpd daemon at boot time. By default, it contains the following options:

DHCPDARGS=value
   Additional options to be passed to the dhcpd daemon. For example:

```
DHCPDARGS=
```

Refer to Chapter 6, Dynamic Host Configuration Protocol (DHCP) for more information on DHCP and its usage.

18.1.6. /etc/sysconfig/firstboot

The /etc/sysconfig/firstboot file defines whether to run the firstboot utility. By default, it contains the following option:

RUN_FIRSTBOOT=boolean
   A boolean to enable (YES) or disable (NO) running the firstboot program. For example:

```
RUN_FIRSTBOOT=NO
```

The first time the system boots, the init program calls the /etc/rc.d/init.d/firstboot script, which looks for the /etc/sysconfig/firstboot file. If this file does not contain the RUN_FIRSTBOOT=NO option, the firstboot program is run, guiding a user through the initial configuration of the system.

Tip: You Can Run the firstboot Program Again

To start the firstboot program the next time the system boots, change the value of RUN_FIRSTBOOT option to YES, and type the following at a shell prompt:

```
~]# chkconfig firstboot on
```
18.1.7. /etc/sysconfig/i18n
The /etc/sysconfig/i18n configuration file defines the default language, any supported languages, and the default system font. By default, it contains the following options:

**LANG=value**
The default language. For example:

```
LANG="en_US.UTF-8"
```

**SUPPORTED=value**
A colon-separated list of supported languages. For example:

```
SUPPORTED="en_US.UTF-8:en_US:en"
```

**SYSFONT=value**
The default system font. For example:

```
SYSFONT="latarcyrheb-sun16"
```

18.1.8. /etc/sysconfig/init
The /etc/sysconfig/init file controls how the system appears and functions during the boot process. By default, it contains the following options:

**BOOTUP=value**
The bootup style. The value has to be either color (the standard color boot display), verbose (an old style display which provides more information), or anything else for the new style display, but without ANSI formatting. For example:

```
BOOTUP=color
```

**RES_COL=value**
The number of the column in which the status labels start. For example:

```
RES_COL=60
```

**MOVE_TO_COL=value**
The terminal sequence to move the cursor to the column specified in RES_COL (see above). For example:

```
MOVE_TO_COL="echo -en \033[\${RES_COL}G"
```

**SETCOLOR_SUCCESS=value**
The terminal sequence to set the success color. For example:

```
SETCOLOR_SUCCESS="echo -en \033[0;32m"
```

**SETCOLOR_FAILURE=value**
The terminal sequence to set the failure color. For example:
Chapter 18. The sysconfig Directory

```bash
SETCOLOR_FAILURE="echo -en \033[0;31m"
```

**SETCOLOR_WARNING=value**
The terminal sequence to set the warning color. For example:

```bash
SETCOLOR_WARNING="echo -en \033[0;33m"
```

**SETCOLOR_NORMAL=value**
The terminal sequence to set the default color. For example:

```bash
SETCOLOR_NORMAL="echo -en \033[0;39m"
```

**LOGLEVEL=value**
The initial console logging level. The value has to be in the range from 1 (kernel panics only) to 8 (everything, including the debugging information). For example:

```bash
LOGLEVEL=3
```

**PROMPT=boolean**
A boolean to enable (yes) or disable (no) the hotkey interactive startup. For example:

```bash
PROMPT=yes
```

**AUTOSWAP=boolean**
A boolean to enable (yes) or disable (no) probing for devices with swap signatures. For example:

```bash
AUTOSWAP=no
```

**ACTIVE_CONSOLES=value**
The list of active consoles. For example:

```bash
ACTIVE_CONSOLES=/dev/tty[1-6]
```

**SINGLE=value**
The single-user mode type. The value has to be either `/sbin/sulogin` (a user will be prompted for a password to log in), or `/sbin/sushell` (the user will be logged in directly). For example:

```bash
SINGLE=/sbin/sushell
```

### 18.1.9. /etc/sysconfig/ip6tables-config

The `/etc/sysconfig/ip6tables-config` file stores information used by the kernel to set up IPv6 packet filtering at boot time or whenever the `ip6tables` service is started. Note that you should not modify it unless you are familiar with `ip6tables` rules. By default, it contains the following options:

**IP6TABLES_MODULES=value**
A space-separated list of helpers to be loaded after the firewall rules are applied. For example:
**IP6TABLES_MODULES**

A boolean to enable (yes) or disable (no) module unloading when the firewall is stopped or restarted. For example:

```
IP6TABLES_MODULES_UNLOAD="yes"
```

**IP6TABLES_SAVE_ON_STOP**

A boolean to enable (yes) or disable (no) saving the current firewall rules when the firewall is stopped. For example:

```
IP6TABLES_SAVE_ON_STOP="no"
```

**IP6TABLES_SAVE_ON_RESTART**

A boolean to enable (yes) or disable (no) saving the current firewall rules when the firewall is restarted. For example:

```
IP6TABLES_SAVE_ON_RESTART="no"
```

**IP6TABLES_SAVE_COUNTER**

A boolean to enable (yes) or disable (no) saving the rule and chain counters. For example:

```
IP6TABLES_SAVE_COUNTER="no"
```

**IP6TABLES_STATUS_NUMERIC**

A boolean to enable (yes) or disable (no) printing IP addresses and port numbers in a numeric format in the status output. For example:

```
IP6TABLES_STATUS_NUMERIC="yes"
```

**IP6TABLES_STATUS_VERBOSE**

A boolean to enable (yes) or disable (no) printing information about the number of packets and bytes in the status output. For example:

```
IP6TABLES_STATUS_VERBOSE="no"
```

**IP6TABLES_STATUS_LINENUMBERS**

A boolean to enable (yes) or disable (no) printing line numbers in the status output. For example:

```
IP6TABLES_STATUS_LINENUMBERS="yes"
```
Chapter 18. The sysconfig Directory

Tip: Use the `ip6tables` Command to Create the Rules

You can create the rules manually using the `ip6tables` command. Once created, type the following at a shell prompt:

```
~]# service ip6tables save
```

This will add the rules to `/etc/sysconfig/ip6tables`. Once this file exists, any firewall rules saved in it persist through a system reboot or a service restart.

18.1.10. `/etc/sysconfig/keyboard`

The `/etc/sysconfig/keyboard` file controls the behavior of the keyboard. By default, it contains the following options:

**KEYTABLE=value**

The name of a keytable file. The files that can be used as keytables start in the `/lib/kbd/keymaps/i386/` directory, and branch into different keyboard layouts from there, all labeled `value.kmap.gz`. The first filename that matches the `KEYTABLE` setting is used. For example:

```
KEYTABLE="us"
```

**MODEL=value**

The keyboard model. For example:

```
MODEL="pc105+inet"
```

**LAYOUT=value**

The keyboard layout. For example:

```
LAYOUT="us"
```

**KEYBOARDTYPE=value**

The keyboard type. Allowed values are `pc` (a PS/2 keyboard), or `sun` (a Sun keyboard). For example:

```
KEYBOARDTYPE="pc"
```

18.1.11. `/etc/sysconfig/ldap`

The `/etc/sysconfig/ldap` file holds the basic configuration for the LDAP server. By default, it contains the following options:

**SLAPD_OPTIONS=value**

Additional options to be passed to the `slapd` daemon. For example:

```
SLAPD_OPTIONS="-4"
```

**SLURPD_OPTIONS=value**

Additional options to be passed to the `slurpd` daemon. For example:
SLURPD_OPTIONS=""

SLAPD_LDAP=boolean
A boolean to enable (yes) or disable (no) using the LDAP over TCP (that is, ldap:///). For example:

SLAPD_LDAP="yes"

SLAPD_LDAPI=boolean
A boolean to enable (yes) or disable (no) using the LDAP over IPC (that is, ldapi:///). For example:

SLAPD_LDAPI="no"

SLAPD_LDAPS=boolean
A boolean to enable (yes) or disable (no) using the LDAP over TLS (that is, ldaps:///). For example:

SLAPD_LDAPS="no"

SLAPD_URLS=value
A space-separated list of URLs. For example:

SLAPD_URLS="ldapi:///var/lib/ldap_root/ldapi ldapi:/// ldaps:///"

SLAPD_SHUTDOWN_TIMEOUT=value
The time to wait for slapd to shut down. For example:

SLAPD_SHUTDOWN_TIMEOUT=3

SLAPD_ULIMIT SETTINGS=value
The parameters to be passed to ulimit before the slapd daemon is started. For example:

SLAPD_ULIMIT_SETTINGS=""

18.1.12. /etc/sysconfig/named
The /etc/sysconfig/named file is used to pass arguments to the named daemon at boot time. By default, it contains the following options:

ROOTDIR=value
The chroot environment under which the named daemon runs. The value has to be a full directory path. For example:

ROOTDIR="/var/named/chroot"

Note that the chroot environment has to be configured first (type info chroot at a shell prompt for more information).
Chapter 18. The sysconfig Directory

OPTIONS=value
Additional options to be passed to named. For example:

```
OPTIONS="-6"
```

Note that you should not use the -t option. Instead, use ROOTDIR as described above.

KEYTAB_FILE=value
The keytab filename. For example:

```
KEYTAB_FILE="/etc/named.keytab"
```

Refer to Chapter 10, The BIND DNS Server for more information on the BIND DNS server and its configuration.

18.1.13. /etc/sysconfig/network
The /etc/sysconfig/network file is used to specify information about the desired network configuration. By default, it contains the following options:

NETWORKING=boolean
A boolean to enable (yes) or disable (no) the networking. For example:

```
NETWORKING=yes
```

HOSTNAME=value
The hostname of the machine. For example:

```
HOSTNAME=penguin.example.com
```

GATEWAY=value
The IP address of the network’s gateway. For example:

```
GATEWAY=192.168.1.0
```

Warning: Avoid Using Custom Init Scripts

Do not use custom init scripts to configure network settings. When performing a post-boot network service restart, custom init scripts configuring network settings that are run outside of the network init script lead to unpredictable results.

18.1.14. /etc/sysconfig/ntpd
The /etc/sysconfig/ntpd file is used to pass arguments to the ntpd daemon at boot time. By default, it contains the following option:

OPTIONS=value
Additional options to be passed to ntpd. For example:

```
OPTIONS="-u ntp:ntp -p /var/run/ntpd.pid -g"
```
Refer to Section 13.1.2, “Network Time Protocol Properties” or Section 13.2.2, “Network Time Protocol Setup” for more information on how to configure the ntpd daemon.

18.1.15. /etc/sysconfig/quagga

The /etc/sysconfig/quagga file holds the basic configuration for Quagga daemons. By default, it contains the following options:

**QCONFDIR=value**
The directory with the configuration files for Quagga daemons. For example:

```
QCONFDIR="/etc/quagga"
```

**BGPD_OPTS=value**
Additional options to be passed to the bgpd daemon. For example:

```
BGPD_OPTS="-A 127.0.0.1 -f ${QCONFDIR}/bgpd.conf"
```

**OSPF6D_OPTS=value**
Additional options to be passed to the ospf6d daemon. For example:

```
OSPF6D_OPTS="-A ::1 -f ${QCONFDIR}/ospf6d.conf"
```

**OSPFD_OPTS=value**
Additional options to be passed to the ospfd daemon. For example:

```
OSPFD_OPTS="-A 127.0.0.1 -f ${QCONFDIR}/ospfd.conf"
```

**RIPD_OPTS=value**
Additional options to be passed to the ripd daemon. For example:

```
RIPD_OPTS="-A 127.0.0.1 -f ${QCONFDIR}/ripd.conf"
```

**RIPNGD_OPTS=value**
Additional options to be passed to the ripngd daemon. For example:

```
RIPNGD_OPTS="-A ::1 -f ${QCONFDIR}/ripngd.conf"
```

**ZEBRA_OPTS=value**
Additional options to be passed to the zebra daemon. For example:

```
ZEBRA_OPTS="-A 127.0.0.1 -f ${QCONFDIR}/zebra.conf"
```

**ISISD_OPTS=value**
Additional options to be passed to the isisd daemon. For example:

```
ISISD_OPTS="-A ::1 -f ${QCONFDIR}/isisd.conf"
```

**WATCH_OPTS=value**
Additional options to be passed to the watchquagga daemon. For example:
Chapter 18. The sysconfig Directory

WATCH_OPTS="-Az -b_ -r/sbin/service_%s_restart -s/sbin/service_%s_start -k/sbin/service_%s_stop"

WATCH_DAEMONS=value
A space separated list of monitored daemons. For example:

WATCH_DAEMONS="zebra bgpd ospfd ospf6d ripd ripngd"

18.1.16. /etc/sysconfig/radvd
The /etc/sysconfig/radvd file is used to pass arguments to the radvd daemon at boot time. By default, it contains the following option:

OPTIONS=value
Additional options to be passed to the radvd daemon. For example:

OPTIONS="-u radvd"

18.1.17. /etc/sysconfig/samba
The /etc/sysconfig/samba file is used to pass arguments to the Samba daemons at boot time. By default, it contains the following options:

SMBDOPTIONS=value
Additional options to be passed to smbd. For example:

SMBDOPTIONS="-D"

NMBDOPTIONS=value
Additional options to be passed to nmbd. For example:

NMBDOPTIONS="-D"

WINBINDOPTIONS=value
Additional options to be passed to winbindd. For example:

WINBINDOPTIONS=""

18.1.18. /etc/sysconfig/selinux
The /etc/sysconfig/selinux file contains the basic configuration options for SELinux. It is a symbolic link to /etc/selinux/config, and by default, it contains the following options:

SELINUX=value
The security policy. The value can be either enforcing (the security policy is always enforced), permissive (instead of enforcing the policy, appropriate warnings are displayed), or disabled (no policy is used). For example:

SELINUX=enforcing
SELINUXTYPE=value
The protection type. The value can be either targeted (the targeted processes are protected), or mls (the Multi Level Security protection). For example:

SELINUXTYPE=targeted

18.1.19. /etc/sysconfig/sendmail
The /etc/sysconfig/sendmail is used to set the default values for the Sendmail application. By default, it contains the following values:

DAEMON=boolean
A boolean to enable (yes) or disable (no) running sendmail as a daemon. For example:

DAEMON=yes

QUEUE=value
The interval at which the messages are to be processed. For example:

QUEUE=1h

Refer to Section 12.3.2, “Sendmail” for more information on Sendmail and its configuration.

18.1.20. /etc/sysconfig/spamassassin
The /etc/sysconfig/spamassassin file is used to pass arguments to the spamd daemon (a daemonized version of Spamassassin) at boot time. By default, it contains the following option:

SPAMDOPTIONS=value
Additional options to be passed to the spamd daemon. For example:

SPAMDOPTIONS="-d -c -m5 -H"

Refer to Section 12.4.2.6, “Spam Filters” for more information on Spamassassin and its configuration.

18.1.21. /etc/sysconfig/squid
The /etc/sysconfig/squid file is used to pass arguments to the squid daemon at boot time. By default, it contains the following options:

SQUID_OPTS=value
Additional options to be passed to the squid daemon. For example:

SQUID_OPTS=""

SQUID_SHUTDOWN_TIMEOUT=value
The time to wait for squid daemon to shut down. For example:

SQUID_SHUTDOWN_TIMEOUT=100

SQUID_CONF=value
The default configuration file. For example:
Chapter 18. The sysconfig Directory

SQUID_CONF="/etc/squid/squid.conf"

18.1.22. /etc/sysconfig/system-config-users

The /etc/sysconfig/system-config-users file is the configuration file for the User Manager utility, and should not be edited by hand. By default, it contains the following options:

**FILTER=boolean**
A boolean to enable (true) or disable (false) filtering of system users. For example:

FILTER=true

**ASSIGN_HIGHEST_UID=boolean**
A boolean to enable (true) or disable (false) assigning the highest available UID to newly added users. For example:

ASSIGN_HIGHEST_UID=true

**ASSIGN_HIGHEST_GID=boolean**
A boolean to enable (true) or disable (false) assigning the highest available GID to newly added groups. For example:

ASSIGN_HIGHEST_GID=true

**PREFER_SAME_UID_GID=boolean**
A boolean to enable (true) or disable (false) using the same UID and GID for newly added users when possible. For example:

PREFER_SAME_UID_GID=true

Refer to Section 15.1, "User and Group Configuration" for more information on User Manager and its usage.

18.1.23. /etc/sysconfig/vncservers

The /etc/sysconfig/vncservers file configures the way the Virtual Network Computing (VNC) server starts up. By default, it contains the following options:

**VNCSERVERS=value**
A list of space separated display:username pairs. For example:

VNCSERVERS="2:myusername"

**VNCSERVERARGS[display]=value**
Additional arguments to be passed to the VNC server running on the specified display. For example:

VNCSERVERARGS[2]="-geometry 800x600 -nolisten tcp -localhost"
18.1.24. /etc/sysconfig/xinetd

The /etc/sysconfig/xinetd file is used to pass arguments to the xinetd daemon at boot time. By default, it contains the following options:

**EXTRAOPTIONS=**value
Additional options to be passed to xinetd. For example:

```
EXTRAOPTIONS=""
```

**XINETD_LANG=**value
The locale information to be passed to every service started by xinetd. Note that to remove locale information from the xinetd environment, you can use an empty string (""") or none. For example:

```
XINETD_LANG="en_US"
```

Refer to Chapter 7, Controlling Access to Services for more information on how to configure the xinetd services.

18.2. Directories in the /etc/sysconfig/ Directory

The following directories are normally found in /etc/sysconfig/.

**/etc/sysconfig/cbq/**
This directory contains the configuration files needed to do Class Based Queuing for bandwidth management on network interfaces. CBQ divides user traffic into a hierarchy of classes based on any combination of IP addresses, protocols, and application types.

**/etc/sysconfig/networking/**
This directory is used by the Network Administration Tool (system-config-network), and its contents should not be edited manually. For more information about configuring network interfaces using the Network Administration Tool, refer to Chapter 5, Network Configuration.

**/etc/sysconfig/network-scripts/**
This directory contains the following network-related configuration files:

- Network configuration files for each configured network interface, such as `ifcfg-eth0` for the eth0 Ethernet interface.
- Scripts used to bring network interfaces up and down, such as `ifup` and `ifdown`.
- Scripts used to bring ISDN interfaces up and down, such as `ifup-isdn` and `ifdown-isdn`.
- Various shared network function scripts which should not be edited directly.

For more information on the /etc/sysconfig/network-scripts/ directory, refer to Chapter 4, Network Interfaces.

**/etc/sysconfig/rhn/**
This directory contains the configuration files and GPG keys for Red Hat Network. No files in this directory should be edited by hand. For more information on Red Hat Network, refer to the Red Hat Network website online at https://rhn.redhat.com/.
18.3. Additional Resources

This chapter is only intended as an introduction to the files in the /etc/sysconfig/ directory. The following source contains more comprehensive information.

18.3.1. Installed Documentation

/usr/share/doc/initscripts-version/sysconfig.txt

A more authoritative listing of the files found in the /etc/sysconfig/ directory and the configuration options available for them.
The proc File System

The Linux kernel has two primary functions: to control access to physical devices on the computer and to schedule when and how processes interact with these devices. The /proc/ directory (also called the proc file system) contains a hierarchy of special files which represent the current state of the kernel, allowing applications and users to peer into the kernel's view of the system.

The /proc/ directory contains a wealth of information detailing system hardware and any running processes. In addition, some of the files within /proc/ can be manipulated by users and applications to communicate configuration changes to the kernel.

Note

Later versions of the 2.6 kernel have made the /proc/ide/ and /proc/pci/ directories obsolete. The /proc/ide/ file system is now superseded by files in sysfs; to retrieve information on PCI devices, use lspci instead. For more information on sysfs or lspci, refer to their respective man pages.

19.1. A Virtual File System

Linux systems store all data as files. Most users are familiar with the two primary types of files: text and binary. But the /proc/ directory contains another type of file called a virtual file. As such, /proc/ is often referred to as a virtual file system.

Virtual files have unique qualities. Most of them are listed as zero bytes in size, but can still contain a large amount of information when viewed. In addition, most of the time and date stamps on virtual files reflect the current time and date, indicative of the fact they are constantly updated.

Virtual files such as /proc/interrupts, /proc/meminfo, /proc/mounts, and /proc/partitions provide an up-to-the-moment glimpse of the system's hardware. Others, like the /proc/filesystems file and the /proc/sys/ directory provide system configuration information and interfaces.

For organizational purposes, files containing information on a similar topic are grouped into virtual directories and sub-directories. Process directories contain information about each running process on the system.

19.1.1. Viewing Virtual Files

Most files within /proc/ files operate similarly to text files, storing useful system and hardware data in human-readable text format. As such, you can use cat, more, or less to view them. For example, to display information about the system's CPU, run cat /proc/cpuinfo. This will return output similar to the following:

```
processor : 0
vendor_id : AuthenticAMD
cpu family : 5
model : 9
model name : AMD-K6(tm) 3D+
Processor stepping : 1 cpu
MHz : 400.919
cache size : 256 KB
fdiv_bug : no
hlt_bug : no
```
Some files in /proc/ contain information that is not human-readable. To retrieve information from such files, use tools such as `lspci`, `apm`, `free`, and `top`.

**Note**
Some of the virtual files in the /proc/ directory are readable only by the root user.

### 19.1.2. Changing Virtual Files
As a general rule, most virtual files within the /proc/ directory are read-only. However, some can be used to adjust settings in the kernel. This is especially true for files in the /proc/sys/ subdirectory.

To change the value of a virtual file, use the following command:

```
echo value > /proc/file
```

For example, to change the hostname on the fly, run:

```
echo www.example.com > /proc/sys/kernel/hostname
```

Other files act as binary or Boolean switches. Typing `cat /proc/sys/net/ipv4/ip_forward` returns either a 0 (off or false) or a 1 (on or true). A 0 indicates that the kernel is not forwarding network packets. To turn packet forwarding on, run `echo 1 > /proc/sys/net/ipv4/ip_forward`.

**Tip**
Another command used to alter settings in the /proc/sys/ subdirectory is `/sbin/sysctl`. For more information on this command, refer to *Section 19.4, “Using the sysctl Command”*

For a listing of some of the kernel configuration files available in the /proc/sys/ subdirectory, refer to *Section 19.3.9, “/proc/sys/”*.

### 19.2. Top-level Files within the proc File System
Below is a list of some of the more useful virtual files in the top-level of the /proc/ directory.

**Note**
In most cases, the content of the files listed in this section are not the same as those installed on your machine. This is because much of the information is specific to the hardware on which Red Hat Enterprise Linux is running for this documentation effort.
19.2.1. /proc/buddyinfo

This file is used primarily for diagnosing memory fragmentation issues. Using the buddy algorithm, each column represents the number of pages of a certain order (a certain size) that are available at any given time. For example, for zone direct memory access (DMA), there are 90 of $2^{(0\times\text{PAGE\_SIZE})}$ chunks of memory. Similarly, there are 6 of $2^{(1\times\text{PAGE\_SIZE})}$ chunks, and 2 of $2^{(2\times\text{PAGE\_SIZE})}$ chunks of memory available.

The DMA row references the first 16 MB on a system, the HighMem row references all memory greater than 4 GB on a system, and the Normal row references all memory in between.

The following is an example of the output typical of /proc/buddyinfo:

```
Node 0, zone      DMA     90      6      2      1      1      ...
Node 0, zone   Normal   1650    310      5      0      0      ...
Node 0, zone  HighMem      2      0      0      1      1      ...
```

19.2.2. /proc/cmdline

This file shows the parameters passed to the kernel at the time it is started. A sample /proc/cmdline file looks like the following:

```
ro root=/dev/VolGroup00/LogVol00 rhgb quiet 3
```

This tells us that the kernel is mounted read-only (signified by (ro)), located on the first logical volume (LogVol00) of the first volume group (/dev/VolGroup00). LogVol00 is the equivalent of a disk partition in a non-LVM system (Logical Volume Management), just as /dev/VolGroup00 is similar in concept to /dev/hda1, but much more extensible.

For more information on LVM used in Red Hat Enterprise Linux, refer to http://www.tldp.org/HOWTO/LVM-HOWTO/index.html.

Next, rhgb signals that the rhgb package has been installed, and graphical booting is supported, assuming /etc/inittab shows a default runlevel set to id:5:initdefault:

Finally, quiet indicates all verbose kernel messages are suppressed at boot time.

19.2.3. /proc/cpuinfo

This virtual file identifies the type of processor used by your system. The following is an example of the output typical of /proc/cpuinfo:

```
processor : 0
vendor_id : GenuineIntel
cpu family : 15
model : 2
model name : Intel(R) Xeon(TM) CPU 2.40GHz
stepping : 7 cpu
Mhz : 2392.371
cache size : 512 KB
physical id : 0
siblings : 2
runqueue : 0
fdiv_bug : no
```

</tr>
<tr>
<td>bogomips</td>
<td>4771.02</td>
</tr>
</tbody>
</table>

- **processor** — Provides each processor with an identifying number. On systems that have one processor, only a 0 is present.

- **cpu family** — Authoritatively identifies the type of processor in the system. For an Intel-based system, place the number in front of “86” to determine the value. This is particularly helpful for those attempting to identify the architecture of an older system such as a 586, 486, or 386. Because some RPM packages are compiled for each of these particular architectures, this value also helps users determine which packages to install.

- **model name** — Displays the common name of the processor, including its project name.

- **cpu MHz** — Shows the precise speed in megahertz for the processor to the thousandths decimal place.

- **cache size** — Displays the amount of level 2 memory cache available to the processor.

- **siblings** — Displays the number of sibling CPUs on the same physical CPU for architectures which use hyper-threading.

- **flags** — Defines a number of different qualities about the processor, such as the presence of a floating point unit (FPU) and the ability to process MMX instructions.

### 19.2.4. /proc/crypto

This file lists all installed cryptographic ciphers used by the Linux kernel, including additional details for each. A sample /proc/crypto file looks like the following:

<table>
<thead>
<tr>
<th>name</th>
<th>sha1</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>
<td>kernel</td>
</tr>
<tr>
<td>type</td>
<td>digest</td>
</tr>
<tr>
<td>blocksize</td>
<td>64</td>
</tr>
<tr>
<td>digestsize</td>
<td>20</td>
</tr>
<tr>
<td>name</td>
<td>md5</td>
</tr>
<tr>
<td>module</td>
<td>md5</td>
</tr>
<tr>
<td>type</td>
<td>digest</td>
</tr>
<tr>
<td>blocksize</td>
<td>64</td>
</tr>
<tr>
<td>digestsize</td>
<td>16</td>
</tr>
</tbody>
</table>

### 19.2.5. /proc/devices

This file displays the various character and block devices currently configured (not including devices whose modules are not loaded). Below is a sample output from this file:

```bash
Character devices:
  1 mem
  4 /dev/vc/0
```
The output from /proc/devices includes the major number and name of the device, and is broken into two major sections: **Character devices** and **Block devices**.

**Character devices** are similar to **block devices**, except for two basic differences:

1. Character devices do not require buffering. Block devices have a buffer available, allowing them to order requests before addressing them. This is important for devices designed to store information — such as hard drives — because the ability to order the information before writing it to the device allows it to be placed in a more efficient order.

2. Character devices send data with no preconfigured size. Block devices can send and receive information in blocks of a size configured per device.

For more information about devices refer to the following installed documentation:

```
/usr/share/doc/kernel-doc-<kernel_version>/Documentation/devices.txt
```

### 19.2.6. /proc/dma

This file contains a list of the registered ISA DMA channels in use. A sample /proc/dma files looks like the following:

```
4: cascade
```

### 19.2.7. /proc/execdomains

This file lists the **execution domains** currently supported by the Linux kernel, along with the range of personalities they support.

```
0-0  Linux  [kernel]
```

Think of execution domains as the "personality" for an operating system. Because other binary formats, such as Solaris, UnixWare, and FreeBSD, can be used with Linux, programmers can change
the way the operating system treats system calls from these binaries by changing the personality of
the task. Except for the PER_LINUX execution domain, different personalities can be implemented as
dynamically loadable modules.

19.2.8. /proc/fb
This file contains a list of frame buffer devices, with the frame buffer device number and the driver that
controls it. Typical output of /proc/fb for systems which contain frame buffer devices looks similar to
the following:

<table>
<thead>
<tr>
<th>Device Number</th>
<th>Driver</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>VESA VGA</td>
</tr>
</tbody>
</table>

19.2.9. /proc/filesystems
This file displays a list of the file system types currently supported by the kernel. Sample output from a
generic /proc/filesystems file looks similar to the following:

```
nodev  sysfs
nodev  rootfs
nodev  bdev
nodev  proc
nodev  sockfs
nodev  bincmt_misc
nodev  usbfs
nodev  usbdevfs
nodev  futexfs
nodev  tmpfs
nodev  pipefs
nodev  eventpollfs
nodev  devpts
ext2
nodev  ramfs
nodev  hugetlbfs
 iso9660
nodev  mqueue
ext3
nodev  rpc_pipefs
nodev  autofs
```

The first column signifies whether the file system is mounted on a block device. Those beginning
with nodev are not mounted on a device. The second column lists the names of the file systems
supported.

The `mount` command cycles through the file systems listed here when one is not specified as an
argument.

19.2.10. /proc/interrupts
This file records the number of interrupts per IRQ on the x86 architecture. A standard /proc/
interrupts looks similar to the following:

```
CPU0
  0: 80448940  XT-PIC timer
  1: 174412  XT-PIC keyboard
  2: 0  XT-PIC cascade
```
For a multi-processor machine, this file may look slightly different:

<table>
<thead>
<tr>
<th>CPU0</th>
<th>CPU1</th>
<th>XT-PIC</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>1366814704</td>
<td>0</td>
<td>timer</td>
</tr>
<tr>
<td>1:</td>
<td>128</td>
<td>340</td>
<td>keyboard</td>
</tr>
<tr>
<td>2:</td>
<td>0</td>
<td>0</td>
<td>cascade</td>
</tr>
<tr>
<td>8:</td>
<td>5323</td>
<td>5793</td>
<td>PS/2 Mouse</td>
</tr>
<tr>
<td>13:</td>
<td>1</td>
<td>0</td>
<td>fpu</td>
</tr>
<tr>
<td>16:</td>
<td>11184294</td>
<td>1594594</td>
<td>Intel EtherExpress Pro 10/100 Ethernet</td>
</tr>
<tr>
<td>19:</td>
<td>8450043</td>
<td>1112093</td>
<td>megaraid</td>
</tr>
<tr>
<td>30:</td>
<td>10432</td>
<td>10722</td>
<td>aic7xxx</td>
</tr>
<tr>
<td>31:</td>
<td>23</td>
<td>22</td>
<td>aic7xxx</td>
</tr>
<tr>
<td>NMI:</td>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ERR:</td>
<td>0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The first column refers to the IRQ number. Each CPU in the system has its own column and its own number of interrupts per IRQ. The next column reports the type of interrupt, and the last column contains the name of the device that is located at that IRQ.

Each of the types of interrupts seen in this file, which are architecture-specific, mean something different. For x86 machines, the following values are common:

- **XT-PIC** — This is the old AT computer interrupts.
- **IO-APIC-edge** — The voltage signal on this interrupt transitions from low to high, creating an edge, where the interrupt occurs and is only signaled once. This kind of interrupt, as well as the **IO-APIC-level** interrupt, are only seen on systems with processors from the 586 family and higher.
- **IO-APIC-level** — Generates interrupts when its voltage signal is high until the signal is low again.

### 19.2.11. /proc/iomem

This file shows you the current map of the system’s memory for each physical device:

```
00000000-0000000 : System RAM
00000000-0000000 : reserved
00000000-0000000 : Video RAM area
00000000-0000000 : Video ROM
00000000-0000000 : System ROM
00100000-07ffffff : System RAM
00100000-00291ba8 : Kernel code
00291ba9-002e09cb : Kernel data
e0000000-0000000 : VIA Technologies, Inc. VT82C597 [Apollo VP3] e4000000-e7ffffff : PCI Bus #0
e4000000-e4000000 : Matrox Graphics, Inc. MGA G200 AGP
e5000000-e5000000 : Matrox Graphics, Inc. MGA G200 AGP
e6000000-e6000000 : Matrox Graphics, Inc. MGA G200 AGP
e7000000-e7000000 : PCI Bus #01
e8000000-e8000000 : Matrox Graphics, Inc. MGA G200 AGP
ea000000-ea000000 : Digital Equipment Corporation DECchip 21140 [FasterNet]
```
Chapter 19. The proc File System

```
| ea000000-ea00007f : tulip | ffff0000-ffffffff : reserved |
```

The first column displays the memory registers used by each of the different types of memory. The second column lists the kind of memory located within those registers and displays which memory registers are used by the kernel within the system RAM or, if the network interface card has multiple Ethernet ports, the memory registers assigned for each port.

### 19.2.12. /proc/ioports

The output of `/proc/ioports` provides a list of currently registered port regions used for input or output communication with a device. This file can be quite long. The following is a partial listing:

```
0000-001f : dma1
0020-003f : pic1
0040-005f : timer
0060-006f : keyboard
0070-007f : rtc
0080-008f : dma page reg
00a0-00bf : pic2
00c0-00df : dma2
00f0-00ff : fpu
0170-0177 : ide1
01f0-01ff : ide0
02f8-02ff : serial(auto)
0376-037f : ide1
03c0-03df : vga+
03f6-03f7 : ide0
03f8-03ff : serial(auto)
0cf8-0cff : PCI conf1
d000-dfff : PCI Bus #01
e000-e00f : VIA Technologies, Inc. Bus Master IDE
e000-e007 : ide0
e008-e00f : ide1
e000-e87f : Digital Equipment Corporation DECchip 21140 [FasterNet]
e800-e87f : tulip
```

The first column gives the I/O port address range reserved for the device listed in the second column.

### 19.2.13. /proc/kcore

This file represents the physical memory of the system and is stored in the core file format. Unlike most `/proc/` files, `kcore` displays a size. This value is given in bytes and is equal to the size of the physical memory (RAM) used plus 4 KB.

The contents of this file are designed to be examined by a debugger, such as `gdb`, and is not human readable.

**Caution**

Do not view the `/proc/kcore` virtual file. The contents of the file scramble text output on the terminal. If this file is accidentally viewed, press `Ctrl+C` to stop the process and then type `reset` to bring back the command line prompt.

### 19.2.14. /proc/kmsg

This file is used to hold messages generated by the kernel. These messages are then picked up by other programs, such as `/sbin/klogd` or `/bin/dmesg`. 
19.2.15. /proc/loadavg

This file provides a look at the load average in regard to both the CPU and IO over time, as well as additional data used by uptime and other commands. A sample /proc/loadavg file looks similar to the following:

```
0.20 0.18 0.12 1/80 11206
```

The first three columns measure CPU and IO utilization of the last one, five, and 15 minute periods. The fourth column shows the number of currently running processes and the total number of processes. The last column displays the last process ID used.

In addition, load average also refers to the number of processes ready to run (i.e. in the run queue, waiting for a CPU share.

19.2.16. /proc/locks

This file displays the files currently locked by the kernel. The contents of this file contain internal kernel debugging data and can vary tremendously, depending on the use of the system. A sample /proc/locks file for a lightly loaded system looks similar to the following:

```
1: POSIX ADVISORY WRITE 3568 fd:00:2531452 0 EOF
2: FLOCK ADVISORY WRITE 3517 fd:00:2531448 0 EOF
3: POSIX ADVISORY WRITE 3452 fd:00:2531442 0 EOF
4: POSIX ADVISORY WRITE 3443 fd:00:2531440 0 EOF
5: POSIX ADVISORY WRITE 3326 fd:00:2531430 0 EOF
6: POSIX ADVISORY WRITE 3175 fd:00:2531425 0 EOF
7: POSIX ADVISORY WRITE 3056 fd:00:2548663 0 EOF
```

Each lock has its own line which starts with a unique number. The second column refers to the class of lock used, with FLOCK signifying the older-style UNIX file locks from a flock system call and POSIX representing the newer POSIX locks from the lockf system call.

The third column can have two values: ADVISORY or MANDATORY. ADVISORY means that the lock does not prevent other people from accessing the data; it only prevents other attempts to lock it. MANDATORY means that no other access to the data is permitted while the lock is held. The fourth column reveals whether the lock is allowing the holder READ or WRITE access to the file. The fifth column shows the ID of the process holding the lock. The sixth column shows the ID of the file being locked, in the format of MAJOR-DEVICE:MINOR-DEVICE:INODE-NUMBER. The seventh and eighth column shows the start and end of the file's locked region.

19.2.17. /proc/mdstat

This file contains the current information for multiple-disk, RAID configurations. If the system does not contain such a configuration, then /proc/mdstat looks similar to the following:

```
Personalities :  read_ahead not set unused devices: <none>
```

This file remains in the same state as seen above unless a software RAID or md device is present. In that case, view /proc/mdstat to find the current status of mdX RAID devices.

The /proc/mdstat file below shows a system with its md0 configured as a RAID 1 device, while it is currently re-syncing the disks:
19.2.18. /proc/meminfo

This is one of the more commonly used files in the /proc/ directory, as it reports a large amount of valuable information about the systems RAM usage.

The following sample /proc/meminfo virtual file is from a system with 256 MB of RAM and 512 MB of swap space:

<table>
<thead>
<tr>
<th>Memory Information</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MemTotal:</td>
<td>255908 kB</td>
</tr>
<tr>
<td>MemFree:</td>
<td>69936 kB</td>
</tr>
<tr>
<td>Buffers:</td>
<td>15812 kB</td>
</tr>
<tr>
<td>Cached:</td>
<td>115124 kB</td>
</tr>
<tr>
<td>SwapCached:</td>
<td>0 kB</td>
</tr>
<tr>
<td>Active:</td>
<td>92700 kB</td>
</tr>
<tr>
<td>Inactive:</td>
<td>63792 kB</td>
</tr>
<tr>
<td>HighTotal:</td>
<td>0 kB</td>
</tr>
<tr>
<td>HighFree:</td>
<td>0 kB</td>
</tr>
<tr>
<td>LowTotal:</td>
<td>255908 kB</td>
</tr>
<tr>
<td>LowFree:</td>
<td>69936 kB</td>
</tr>
<tr>
<td>SwapTotal:</td>
<td>524280 kB</td>
</tr>
<tr>
<td>SwapFree:</td>
<td>524280 kB</td>
</tr>
<tr>
<td>Dirty:</td>
<td>4 kB</td>
</tr>
<tr>
<td>Writeback:</td>
<td>0 kB</td>
</tr>
<tr>
<td>Mapped:</td>
<td>42236 kB</td>
</tr>
<tr>
<td>Slab:</td>
<td>25912 kB</td>
</tr>
<tr>
<td>Committed_AS:</td>
<td>118680 kB</td>
</tr>
<tr>
<td>PageTables:</td>
<td>1236 kB</td>
</tr>
<tr>
<td>VmallocTotal:</td>
<td>3874808 kB</td>
</tr>
<tr>
<td>VmallocUsed:</td>
<td>1416 kB</td>
</tr>
<tr>
<td>VmallocChunk:</td>
<td>3872908 kB</td>
</tr>
<tr>
<td>HugePages_Total:</td>
<td>0</td>
</tr>
<tr>
<td>HugePages_Free:</td>
<td>0</td>
</tr>
<tr>
<td>Hugepagesize:</td>
<td>4096 kB</td>
</tr>
</tbody>
</table>

Much of the information here is used by the free, top, and ps commands. In fact, the output of the free command is similar in appearance to the contents and structure of /proc/meminfo. But by looking directly at /proc/meminfo, more details are revealed:

- **MemTotal** — Total amount of physical RAM, in kilobytes.
- **MemFree** — The amount of physical RAM, in kilobytes, left unused by the system.
- **Buffers** — The amount of physical RAM, in kilobytes, used for file buffers.
- **Cached** — The amount of physical RAM, in kilobytes, used as cache memory.
- **SwapCached** — The amount of swap, in kilobytes, used as cache memory.
- **Active** — The total amount of buffer or page cache memory, in kilobytes, that is in active use. This is memory that has been recently used and is usually not reclaimed for other purposes.
- **Inactive** — The total amount of buffer or page cache memory, in kilobytes, that are free and available. This is memory that has not been recently used and can be reclaimed for other purposes.
• **HighTotal** and **HighFree** — The total and free amount of memory, in kilobytes, that is not directly mapped into kernel space. The **HighTotal** value can vary based on the type of kernel used.

• **LowTotal** and **LowFree** — The total and free amount of memory, in kilobytes, that is directly mapped into kernel space. The **LowTotal** value can vary based on the type of kernel used.

• **SwapTotal** — The total amount of swap available, in kilobytes.

• **SwapFree** — The total amount of swap free, in kilobytes.

• **Dirty** — The total amount of memory, in kilobytes, waiting to be written back to the disk.

• **Writeback** — The total amount of memory, in kilobytes, actively being written back to the disk.

• **Mapped** — The total amount of memory, in kilobytes, which have been used to map devices, files, or libraries using the `mmap` command.

• **Slab** — The total amount of memory, in kilobytes, used by the kernel to cache data structures for its own use.

• **Committed_AS** — The total amount of memory, in kilobytes, estimated to complete the workload. This value represents the worst case scenario value, and also includes swap memory.

• **PageTables** — The total amount of memory, in kilobytes, dedicated to the lowest page table level.

• **VMallocTotal** — The total amount of memory, in kilobytes, of total allocated virtual address space.

• **VMallocUsed** — The total amount of memory, in kilobytes, of used virtual address space.

• **VMallocChunk** — The largest contiguous block of memory, in kilobytes, of available virtual address space.

• **HugePages_Total** — The total number of hugepages for the system. The number is derived by dividing **Hugepagesize** by the megabytes set aside for hugepages specified in `/proc/sys/vm/hugetlb_pool`. *This statistic only appears on the x86, Itanium, and AMD64 architectures.*

• **HugePages_Free** — The total number of hugepages available for the system. *This statistic only appears on the x86, Itanium, and AMD64 architectures.*

• **Hugepagesize** — The size for each hugepages unit in kilobytes. By default, the value is 4096 KB on uniprocessor kernels for 32 bit architectures. For SMP, hugemem kernels, and AMD64, the default is 2048 KB. For Itanium architectures, the default is 262144 KB. *This statistic only appears on the x86, Itanium, and AMD64 architectures.*

### 19.2.19. /proc/misc

This file lists miscellaneous drivers registered on the miscellaneous major device, which is device number 10:

```
63  device-mapper 175  agpgart 135  rtc 134  apm_bios
```

The first column is the minor number of each device, while the second column shows the driver in use.
19.2.20. /proc/modules

This file displays a list of all modules loaded into the kernel. Its contents vary based on the configuration and use of your system, but it should be organized in a similar manner to this sample /proc/modules file output:

```
Note
This example has been reformatted into a readable format. Most of this information can also be viewed via the /sbin/lsmod command.
```

```
<table>
<thead>
<tr>

<tr>
<td>ext3</td>
<td>92585</td>
<td>2</td>
<td></td>
<td>Live</td>
<td>0x12886000</td>
</tr>
<tr>
<td>jbd</td>
<td>65625</td>
<td>1 ext3</td>
<td></td>
<td>Live</td>
<td>0x12857000</td>
</tr>
<tr>
<td>dm_mod</td>
<td>46677</td>
<td>3</td>
<td></td>
<td>Live</td>
<td>0x12833000</td>
</tr>
</tbody>
</table>
```

The first column contains the name of the module.

The second column refers to the memory size of the module, in bytes.

The third column lists how many instances of the module are currently loaded. A value of zero represents an unloaded module.

The fourth column states if the module depends upon another module to be present in order to function, and lists those other modules.

The fifth column lists what load state the module is in: **Live**, **Loading**, or **Unloading** are the only possible values.

The sixth column lists the current kernel memory offset for the loaded module. This information can be useful for debugging purposes, or for profiling tools such as `oprofile`.

19.2.21. /proc/mounts

This file provides a list of all mounts in use by the system:

```
rootfs / rootfs rw 0 0
/proc /proc proc rw,nodiratime 0 0 none
/dev ramfs rw 0 0
/dev/mapper/VolGroup00-LogVol00 / ext3 rw 0 0
none /dev ramfs rw 0 0
/proc /proc proc rw,nodiratime 0 0
/sys /sys sysfs rw 0 0
none /dev/pts devpts rw 0 0
usbdevfs /proc/bus/usb usbdevfs rw 0 0
```
The output found here is similar to the contents of /etc/mtab, except that /proc/mounts is more up-to-date.

The first column specifies the device that is mounted, the second column reveals the mount point, and the third column tells the file system type, and the fourth column tells you if it is mounted read-only (ro) or read-write (rw). The fifth and sixth columns are dummy values designed to match the format used in /etc/mtab.

19.2.22. /proc/mtrr

This file refers to the current Memory Type Range Registers (MTRRs) in use with the system. If the system architecture supports MTRRs, then the /proc/mtrr file may look similar to the following:

```
reg00: base=0x00000000 ( 0MB), size= 256MB: write-back, count=1
reg01: base=0xe8000000 (3712MB), size= 32MB: write-combining, count=1
```

MTRRs are used with the Intel P6 family of processors (Pentium II and higher) and control processor access to memory ranges. When using a video card on a PCI or AGP bus, a properly configured /proc/mtrr file can increase performance more than 150%.

Most of the time, this value is properly configured by default. More information on manually configuring this file can be found locally at the following location:

```
/usr/share/doc/kernel-doc-<kernel_version>/Documentation/<arch>/mtrr.txt
```

19.2.23. /proc/partitions

This file contains partition block allocation information. A sampling of this file from a basic system looks similar to the following:

```
major minor  #blocks  name
 3     0   19531250 hda
 3     1    104391 hda1
 3     2   19422585 hda2
253     0   22708224 dm-0
253     1    524288 dm-1
```

Most of the information here is of little importance to the user, except for the following columns:

- **major** — The major number of the device with this partition. The major number in the /proc/partitions, (3), corresponds with the block device ide0, in /proc/devices.
- **minor** — The minor number of the device with this partition. This serves to separate the partitions into different physical devices and relates to the number at the end of the name of the partition.
- **#blocks** — Lists the number of physical disk blocks contained in a particular partition.
- **name** — The name of the partition.
19.2.24. /proc/slabinfo

This file gives full information about memory usage on the slab level. Linux kernels greater than version 2.2 use slab pools to manage memory above the page level. Commonly used objects have their own slab pools.

Instead of parsing the highly verbose /proc/slabinfo file manually, the /usr/bin/slabtop program displays kernel slab cache information in real time. This program allows for custom configurations, including column sorting and screen refreshing.

A sample screen shot of /usr/bin/slabtop usually looks like the following example:

```
Active / Total Objects (% used)    : 133629 / 147300 (90.7%)
Active / Total Slabs (% used)      : 11492 / 11493 (100.0%)
Active / Total Caches (% used)     : 77 / 121 (63.6%)

```

Some of the more commonly used statistics in /proc/slabinfo that are included into /usr/bin/slabtop include:

- **OBJS** — The total number of objects (memory blocks), including those in use (allocated), and some spares not in use.
- **ACTIVE** — The number of objects (memory blocks) that are in use (allocated).
- **USE** — The percentage of total objects that are active. ((ACTIVE/OBJS)(100))
- **OBJ SIZE** — The size of the objects.
- **SLABS** — The total number of slabs.
- **OBJ/SLAB** — The number of objects that fit into a slab.
- **CACHE SIZE** — The cache size of the slab.
- **NAME** — The name of the slab.
For more information on the `/usr/bin/slabtop` program, refer to the `slabtop` man page.

### 19.2.25. `/proc/stat`

This file keeps track of a variety of different statistics about the system since it was last restarted. The contents of `/proc/stat`, which can be quite long, usually begins like the following example:

```
cpu  259246  7001  60190  34250993  137517  772  0
cpu0 259246  7001  60190  34250993  137517  772  0
intr 354133732 347209999  2272  0  4  4  0  3  1 1249247  0  0  80143  0  422626  5169433
cxt  12547729
btime  1093631447
processes  130523
procs_running  1
procs_blocked  0
preempt  5651840
```

Some of the more commonly used statistics include:

- **cpu** — Measures the number of jiffies (1/100 of a second for x86 systems) that the system has been in user mode, user mode with low priority (nice), system mode, idle task, I/O wait, IRQ (hardirq), and softirq respectively. The IRQ (hardirq) is the direct response to a hardware event. The IRQ takes minimal work for queuing the “heavy” work up for the softirq to execute. The softirq runs at a lower priority than the IRQ and therefore may be interrupted more frequently. The total for all CPUs is given at the top, while each individual CPU is listed below with its own statistics. The following example is a 4-way Intel Pentium Xeon configuration with multi-threading enabled, therefore showing four physical processors and four virtual processors totaling eight processors.

- **page** — The number of memory pages the system has written in and out to disk.

- **swap** — The number of swap pages the system has brought in and out.

- **intr** — The number of interrupts the system has experienced.

- **btime** — The boot time, measured in the number of seconds since January 1, 1970, otherwise known as the **epoch**.

### 19.2.26. `/proc/swaps`

This file measures swap space and its utilization. For a system with only one swap partition, the output of `/proc/swaps` may look similar to the following:

<table>
<thead>
<tr>
<th>Filename</th>
<th>Type</th>
<th>Size</th>
<th>Used</th>
<th>Priority</th>
</tr>
</thead>
</table>

---

321
Chapter 19. The proc File System

While some of this information can be found in other files in the /proc/ directory, /proc/swap provides a snapshot of every swap file name, the type of swap space, the total size, and the amount of space in use (in kilobytes). The priority column is useful when multiple swap files are in use. The lower the priority, the more likely the swap file will be used.

19.2.27. /proc/sysrq-trigger

Using the echo command to write to this file, a remote root user can execute most System Request Key commands remotely as if at the local terminal. To echo values to this file, the /proc/sys/kernel/sysrq must be set to a value other than 0. For more information about the System Request Key, refer to Section 19.3.9.3, “/proc/sys/kernel/”.

 Although it is possible to write to this file, it cannot be read, even by the root user.

19.2.28. /proc/uptime

This file contains information detailing how long the system has been on since its last restart. The output of /proc/uptime is quite minimal:

```
350735.47 234388.90
```

The first number is the total number of seconds the system has been up. The second number is how much of that time the machine has spent idle, in seconds.

19.2.29. /proc/version

This file specifies the version of the Linux kernel, the version of gcc used to compile the kernel, and the time of kernel compilation. It also contains the kernel compiler's user name (in parentheses).

```
Linux version 2.6.8-1.523 (user@foo.redhat.com) (gcc version 3.4.1 20040714 \ (Red Hat Enterprise Linux 3.4.1-7)) #1 Mon Aug 16 13:27:03 EDT 2004
```

This information is used for a variety of purposes, including the version data presented when a user logs in.

19.3. Directories within /proc/

Common groups of information concerning the kernel are grouped into directories and subdirectories within the /proc/ directory.

19.3.1. Process Directories

Every /proc/ directory contains a number of directories with numerical names. A listing of them may be similar to the following:

```
    dr-xr-xr-x  3 root    root          0 Feb 13 01:28 1
    dr-xr-xr-x  3 root    root          0 Feb 13 01:28 1010
    dr-xr-xr-x  3 xfs     xfs           0 Feb 13 01:28 1087
    dr-xr-xr-x  3 daemon  daemon       0 Feb 13 01:28 1123
    dr-xr-xr-x  3 root    root          0 Feb 13 01:28 11307
```
These directories are called *process directories*, as they are named after a program's process ID and contain information specific to that process. The owner and group of each process directory is set to the user running the process. When the process is terminated, its */proc/* process directory vanishes.

Each process directory contains the following files:

- **cmdline** — Contains the command issued when starting the process.

- **cwd** — A symbolic link to the current working directory for the process.

- **environ** — A list of the environment variables for the process. The environment variable is given in all upper-case characters, and the value is in lower-case characters.

- **exe** — A symbolic link to the executable of this process.

- **fd** — A directory containing all of the file descriptors for a particular process. These are given in numbered links:

  ```
  total 0
  lrwx------ 1 root  root  64 May  8 11:31 0 -> /dev/null
  lrwx------ 1 root  root  64 May  8 11:31 1 -> /dev/null
  lrwx------ 1 root  root  64 May  8 11:31 2 -> /dev/null
  lrwx------ 1 root  root  64 May  8 11:31 3 -> /dev/ptmx
  lrwx------ 1 root  root  64 May  8 11:31 4 -> socket:[7774817]
  lrwx------ 1 root  root  64 May  8 11:31 5 -> /dev/ptmx
  lrwx------ 1 root  root  64 May  8 11:31 6 -> socket:[7774829]
  lrwx------ 1 root  root  64 May  8 11:31 7 -> /dev/ptmx
  ```

- **maps** — A list of memory maps to the various executables and library files associated with this process. This file can be rather long, depending upon the complexity of the process, but sample output from the *sshd* process begins like the following:

  ```
  00048000-00086000 r-xp 00000000 03:03 391479 /usr/sbin/sshd
  00086000-00088000 rw-p 0003e000 03:03 391479 /usr/sbin/sshd
  00088000-00095000 rwxp 00000000 00:00 0
  40000000-40013000 r-xp 00000000 03:03 293205 /lib/ld-2.2.5.so
  40013000-40014000 rw-p 00013000 03:03 293205 /lib/ld-2.2.5.so
  40031000-40038000 r-xp 00000000 03:03 293282 /lib/libpam.so.0.75
  40038000-40039000 rw-p 00006000 03:03 293282 /lib/libpam.so.0.75
  40039000-4003c000 r-xp 00000000 00:00 0
  4003c000-4003d000 rw-p 00001000 03:03 293218 /lib/libdl-2.2.5.so
  4003d000-4003e000 rw-p 00000000 03:03 293218 /lib/libdl-2.2.5.so
  ```

- **mem** — The memory held by the process. This file cannot be read by the user.

- **root** — A link to the root directory of the process.

- **stat** — The status of the process.

- **statm** — The status of the memory in use by the process. Below is a sample */proc/statm* file:

  ```
  263 210 210 5 0 205 0
  ```
The seven columns relate to different memory statistics for the process. From left to right, they report the following aspects of the memory used:

1. Total program size, in kilobytes.
2. Size of memory portions, in kilobytes.
3. Number of pages that are shared.
4. Number of pages that are code.
5. Number of pages of data/stack.
6. Number of library pages.
7. Number of dirty pages.

- **status** — The status of the process in a more readable form than `stat` or `statm`. Sample output for `sshd` looks similar to the following:

```
Name: sshd
State: S (sleeping)
Tgid: 797
Pid: 797
PPid: 1
TracerPid: 0
Uid: 0 0 0 0
Gid: 0 0 0 0
FDSize: 32
Groups:
VmSize:     3072 kB
VmLck:        0 kB
VmRSS:      840 kB
VmData:      104 kB
VmStk:       12 kB
VmExe:      300 kB
VmLib:     2528 kB
SigPnd: 0000000000000000
SigBlk: 0000000000000000
SigIgn: 8000000000100000
SigCgt: 0000000000014005
CapInh: 0000000000000000
CapPrm: 00000000fffffff
CapEff: 00000000fffffff
```

The information in this output includes the process name and ID, the state (such as S (sleeping) or R (running)), user/group ID running the process, and detailed data regarding memory usage.

**19.3.1.1. /proc/self/**

The `/proc/self/` directory is a link to the currently running process. This allows a process to look at itself without having to know its process ID.

Within a shell environment, a listing of the `/proc/self/` directory produces the same contents as listing the process directory for that process.
19.3.2. /proc/bus/

This directory contains information specific to the various buses available on the system. For example, on a standard system containing PCI and USB buses, current data on each of these buses is available within a subdirectory within /proc/bus/ by the same name, such as /proc/bus/pci/.

The subdirectories and files available within /proc/bus/ vary depending on the devices connected to the system. However, each bus type has at least one directory. Within these bus directories are normally at least one subdirectory with a numerical name, such as 001, which contain binary files.

For example, the /proc/bus/usb/ subdirectory contains files that track the various devices on any USB buses, as well as the drivers required for them. The following is a sample listing of a /proc/bus/usb/ directory:

```
  total 0  dr-xr-xr-x   1  root   root 0 May 3 16:25 001
  -r--r--r--   1  root   root 0 May 3 16:25 devices
  -r--r--r--   1  root   root 0 May 3 16:25 drivers
```

The /proc/bus/usb/001/ directory contains all devices on the first USB bus and the devices file identifies the USB root hub on the motherboard.

The following is an example of a /proc/bus/usb/devices file:

```
T: Bus=01 Lev=00 Prnt=00 Port=00 Cnt=00 Dev#= 1 Spd=12 MxCh= 2
B: Alloc= 0/900 us ( 0%), #Int= 0, #Iso= 0
D: Ver= 1.00 Cls=09(hub ) Sub=00 Prot=00 MxPS= 8 #Cfgs= 1
P: Vendor=0000 ProdID=0000 Rev= 0.00
S: Product=USB UHCI Root Hub
S: SerialNumber=d400
C:* #Ifs= 1 Cfg#= 1 Atr=40 MxPwr= 0mA
I: If#= 0 Alt= 0 #EPs= 1 Cls=09(hub ) Sub=00 Prot=00 Driver=hub
E: Ad=81(I) Atr=03(Int.) MxPwr= 8 Iv=255ms
```

19.3.3. /proc/bus/pci

Later versions of the 2.6 Linux kernel have obsoleted the /proc/pci directory in favor of the /proc/bus/pci directory. Although you can get a list of all PCI devices present on the system using the command cat /proc/bus/pci/devices, the output is difficult to read and interpret.

For a human-readable list of PCI devices, run the following command:

```
-]# /sbin/lspci -vb
00:00.0 Host bridge: Intel Corporation 82X38/X48 Express DRAM Controller
   Subsystem: Hewlett-Packard Company Device 1308
   Flags: bus master, fast devsel, latency 0
   Capabilities: [e0] Vendor Specific Information <>
   Kernel driver in use: x38_edac
   Kernel modules: x38_edac

00:01.0 PCI bridge: Intel Corporation 82X38/X48 Express Host-Primary PCI Express Bridge
   (prog-if 00 [Normal decode])
   Flags: bus master, fast devsel, latency 0
   Bus: primary=00, secondary=01, subordinate=01, sec-latency=0
   I/O behind bridge: 00001000-00001fff
   Memory behind bridge: f0000000-ffffffff
   Capabilities: [80] Subsystem: Hewlett-Packard Company Device 1308
   Capabilities: [80] Power Management version 3
   Capabilities: [90] MSI: Enable= Count=1/1 Maskable- 64bit-
   Capabilities: [a0] Express Root Port (Slot+), MSI 00
```
Chapter 19. The proc File System

The output is a sorted list of all IRQ numbers and addresses as seen by the cards on the PCI bus instead of as seen by the kernel. Beyond providing the name and version of the device, this list also gives detailed IRQ information so an administrator can quickly look for conflicts.

19.3.4. /proc/driver/

This directory contains information for specific drivers in use by the kernel.

A common file found here is rtc which provides output from the driver for the system’s Real Time Clock (RTC), the device that keeps the time while the system is switched off. Sample output from /proc/driver/rtc looks like the following:

```
rtc_time : 16:21:00
rtc_date : 2004-08-31
rtc_epoch : 1900
alarm : 21:16:27
DST_enable : no
BCD : yes
24hr : yes
square_wave : no
alarm_IRQ : no
update_IRQ : no
periodic_IRQ : no
periodic_freq : 1024
batt_status : okay
```

For more information about the RTC, refer to the following installed documentation:

```
```

19.3.5. /proc/fs

This directory shows which file systems are exported. If running an NFS server, typing `cat /proc/fs/nfsd/exports` displays the file systems being shared and the permissions granted for those file systems. For more on file system sharing with NFS, refer to the Network File System (NFS) chapter of the Storage Administration Guide.

19.3.6. /proc/irq/

This directory is used to set IRQ to CPU affinity, which allows the system to connect a particular IRQ to only one CPU. Alternatively, it can exclude a CPU from handling any IRQs.

Each IRQ has its own directory, allowing for the individual configuration of each IRQ. The `/proc/irq/prof_cpu_mask` file is a bitmask that contains the default values for the `smp_affinity` file in the IRQ directory. The values in `smp_affinity` specify which CPUs handle that particular IRQ.
For more information about the `/proc/irq/` directory, refer to the following installed documentation:

```
/usr/share/doc/kernel-doc-kernel_version/Documentation/filesystems/proc.txt
```

### 19.3.7. /proc/net/

This directory provides a comprehensive look at various networking parameters and statistics. Each directory and virtual file within this directory describes aspects of the system’s network configuration. Below is a partial list of the `/proc/net/` directory:

- **arp** — Lists the kernel's ARP table. This file is particularly useful for connecting a hardware address to an IP address on a system.
- **atm/ directory** — The files within this directory contain Asynchronous Transfer Mode (ATM) settings and statistics. This directory is primarily used with ATM networking and ADSL cards.
- **dev** — Lists the various network devices configured on the system, complete with transmit and receive statistics. This file displays the number of bytes each interface has sent and received, the number of packets inbound and outbound, the number of errors seen, the number of packets dropped, and more.
- **dev_mcast** — Lists Layer2 multicast groups on which each device is listening.
- **igmp** — Lists the IP multicast addresses which this system joined.
- **ip_conntrack** — Lists tracked network connections for machines that are forwarding IP connections.
- **ip_tables_names** — Lists the types of `iptables` in use. This file is only present if `iptables` is active on the system and contains one or more of the following values: `filter`, `mangle`, or `nat`.
- **ip_mr_cache** — Lists the multicast routing cache.
- **ip_mr_vif** — Lists multicast virtual interfaces.
- **netstat** — Contains a broad yet detailed collection of networking statistics, including TCP timeouts, SYN cookies sent and received, and much more.
- **psched** — Lists global packet scheduler parameters.
- **raw** — Lists raw device statistics.
- **route** — Lists the kernel's routing table.
- **rt_cache** — Contains the current routing cache.
- **snmp** — List of Simple Network Management Protocol (SNMP) data for various networking protocols in use.
- **sockstat** — Provides socket statistics.
- **tcp** — Contains detailed TCP socket information.
- **tr_rif** — Lists the token ring RIF routing table.
- **udp** — Contains detailed UDP socket information.
Chapter 19. The proc File System

- **unix** — Lists UNIX domain sockets currently in use.
- **wireless** — Lists wireless interface data.

### 19.3.8. /proc/scsi/

The primary file in this directory is `/proc/scsi/scsi`, which contains a list of every recognized SCSI device. From this listing, the type of device, as well as the model name, vendor, SCSI channel and ID data is available.

For example, if a system contains a SCSI CD-ROM, a tape drive, a hard drive, and a RAID controller, this file looks similar to the following:

```
Attached devices:
Host: scsi1
Channel: 00
Id: 05
Lun: 00
Vendor: NEC
Model: CD-ROM DRIVE:466
Rev: 1.06
Type: CD-ROM
ANSI SCSI revision: 02

Host: scsi1
Channel: 00
Id: 06
Lun: 00
Vendor: ARCHIVE
Model: Python 04106-XXX
Rev: 7350
Type: Sequential-Access
ANSI SCSI revision: 02

Host: scsi2
Channel: 00
Id: 06
Lun: 00
Vendor: DELL
Model: 1x6 U2W SCSI BP
Rev: 5.35
Type: Processor
ANSI SCSI revision: 02

Host: scsi2
Channel: 02
Id: 00
Lun: 00
Vendor: MegaRAID
Model: LD0 RAID5 34556R
Rev: 1.01
Type: Direct-Access
ANSI SCSI revision: 02
```

Each SCSI driver used by the system has its own directory within `/proc/scsi/`, which contains files specific to each SCSI controller using that driver. From the previous example, `aic7xxx/` and `megaraid/` directories are present, since two drivers are in use. The files in each of the directories typically contain an I/O address range, IRQ information, and statistics for the SCSI controller using that driver. Each controller can report a different type and amount of information. The Adaptec AIC-7880 Ultra SCSI host adapter's file in this example system produces the following output:

```
Adaptec AIC7xxx driver version: 5.1.20/3.2.4
Compile Options:
```
TCQ Enabled By Default  : Disabled
AIC7XXX_PROC_STATS  : Enabled
AIC7XXX_RESET_DELAY : 5

Adapter Configuration:
SCSI Adapter: Adaptec AIC-7880 Ultra SCSI host adapter
Ultra Narrow Controller  PCI MMAPed
I/O Base: 0xfcffe000
Adapter SEEPROM Config: SEEPROM found and used.
Adaptec SCSI BIOS: Enabled
IRQ: 30
SCBs: Active 0, Max Active 1, Allocated 15, HW 16, Page 255
Interrupts: 33726
BIOS Control Word: 0x18a6
Adapter Control Word: 0x1c5f
Extended Translation: Enabled
Disconnected Enable Flags: 0x00ff
Ultra Enable Flags: 0x0020
Tag Queue Enable Flags: 0x0000
Ordered Queue Tag Flags: 0x0000
Default Tag Queue Depth: 8
Tagged Queue By Device array for aic7xxx
Actual queue depth per device for aic7xxx host instance 1:
{1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1}

Statistics:

(scsl:0:5:0) Device using Narrow/Sync transfers at 20.0 MByte/sec, offset 15
Transinfo settings: current(12/15/0/0), goal(12/15/0/0), user(12/15/0/0)
Total transfers 0 (0 reads and 0 writes)
< 2K    2K+    4K+    8K+    16K+    32K+    64K+    128K+
Reads:  0      0      0      0      0      0      0      0
Writes:  0      0      0      0      0      0      0      0

(scsl:0:6:0) Device using Narrow/Sync transfers at 10.0 MByte/sec, offset 15
Transinfo settings: current(25/15/0/0), goal(12/15/0/0), user(12/15/0/0)
Total transfers 132 (0 reads and 132 writes)
< 2K    2K+    4K+    8K+    16K+    32K+    64K+    128K+
Reads:  0      0      0      0      0      0      0      0
Writes:  0      0      0      1  131     0      0      0

This output reveals the transfer speed to the SCSI devices connected to the controller based on channel ID, as well as detailed statistics concerning the amount and sizes of files read or written by that device. For example, this controller is communicating with the CD-ROM at 20 megabytes per second, while the tape drive is only communicating at 10 megabytes per second.

19.3.9. /proc/sys/

The /proc/sys/ directory is different from others in /proc/ because it not only provides information about the system but also allows the system administrator to immediately enable and disable kernel features.

Caution

Use caution when changing settings on a production system using the various files in the /proc/sys/ directory. Changing the wrong setting may render the kernel unstable, requiring a system reboot.

For this reason, be sure the options are valid for that file before attempting to change any value in /proc/sys/.
A good way to determine if a particular file can be configured, or if it is only designed to provide information, is to list it with the `-l` option at the shell prompt. If the file is writable, it may be used to configure the kernel. For example, a partial listing of `/proc/sys/fs` looks like the following:

```
-r--r--r--    1 root     root            0 May 10 16:14 dentry-state
-rw-r--r--    1 root     root            0 May 10 16:14 dir-notify-enable
-rw-r--r--    1 root     root            0 May 10 16:14 file-max
-r--r--r--    1 root     root            0 May 10 16:14 file-nr
```

In this listing, the files `dir-notify-enable` and `file-max` can be written to and, therefore, can be used to configure the kernel. The other files only provide feedback on current settings.

Changing a value within a `/proc/sys/` file is done by echoing the new value into the file. For example, to enable the System Request Key on a running kernel, type the command:

```
echo 1 > /proc/sys/kernel/sysrq
```

This changes the value for `sysrq` from 0 (off) to 1 (on).

A few `/proc/sys/` configuration files contain more than one value. To correctly send new values to them, place a space character between each value passed with the `echo` command, such as is done in this example:

```
echo 4 2 45 > /proc/sys/kernel/acct
```

**Note**

Any configuration changes made using the `echo` command disappear when the system is restarted. To make configuration changes take effect after the system is rebooted, refer to Section 19.4, “Using the `sysctl` Command”.

The `/proc/sys/` directory contains several subdirectories controlling different aspects of a running kernel.

**19.3.9.1. /proc/sys/dev/**

This directory provides parameters for particular devices on the system. Most systems have at least two directories, `cdrom/` and `raid/`. Customized kernels can have other directories, such as `parport/`, which provides the ability to share one parallel port between multiple device drivers.

The `cdrom/` directory contains a file called `info`, which reveals a number of important CD-ROM parameters:

```
CD-ROM information, Id: cdrom.c 3.20 2003/12/17
drive name:            hdc
drive speed:           48
drive # of slots:       1
Can close tray:        1
Can open tray:         1
Can lock tray:         1
Can change speed:      1
```
This file can be quickly scanned to discover the qualities of an unknown CD-ROM. If multiple CD-ROMs are available on a system, each device is given its own column of information.

Various files in `/proc/sys/dev/cdrom`, such as `autoclose` and `checkmedia`, can be used to control the system's CD-ROM. Use the `echo` command to enable or disable these features.

If RAID support is compiled into the kernel, a `/proc/sys/dev/raid/` directory becomes available with at least two files in it: `speed_limit_min` and `speed_limit_max`. These settings determine the acceleration of RAID devices for I/O intensive tasks, such as resyncing the disks.

### 19.3.9.2. `/proc/sys/fs/`

This directory contains an array of options and information concerning various aspects of the file system, including quota, file handle, inode, and dentry information.

The `binfmt_misc/` directory is used to provide kernel support for miscellaneous binary formats.

The important files in `/proc/sys/fs/` include:

- **dentry-state** — Provides the status of the directory cache. The file looks similar to the following:

```
57411 52939 45 0 0 0
```

The first number reveals the total number of directory cache entries, while the second number displays the number of unused entries. The third number tells the number of seconds between when a directory has been freed and when it can be reclaimed, and the fourth measures the pages currently requested by the system. The last two numbers are not used and display only zeros.

- **file-max** — Lists the maximum number of file handles that the kernel allocates. Raising the value in this file can resolve errors caused by a lack of available file handles.

- **file-nr** — Lists the number of allocated file handles, used file handles, and the maximum number of file handles.

- **overflowgid** and **overflowuid** — Defines the fixed group ID and user ID, respectively, for use with file systems that only support 16-bit group and user IDs.

### 19.3.9.3. `/proc/sys/kernel/`

This directory contains a variety of different configuration files that directly affect the operation of the kernel. Some of the most important files include:

- **acct** — Controls the suspension of process accounting based on the percentage of free space available on the file system containing the log. By default, the file looks like the following:
The first value dictates the percentage of free space required for logging to resume, while the second value sets the threshold percentage of free space when logging is suspended. The third value sets the interval, in seconds, that the kernel polls the file system to see if logging should be suspended or resumed.

- **ctrl-alt-del** — Controls whether Ctrl+Alt+Delete gracefully restarts the computer using `init (0)` or forces an immediate reboot without syncing the dirty buffers to disk (1).

- **domainname** — Configures the system domain name, such as `example.com`.

- **exec-shield** — Configures the Exec Shield feature of the kernel. Exec Shield provides protection against certain types of buffer overflow attacks.

There are two possible values for this virtual file:

- **0** — Disables Exec Shield.
- **1** — Enables Exec Shield. This is the default value.

**Important**

If a system is running security-sensitive applications that were started while Exec Shield was disabled, these applications must be restarted when Exec Shield is enabled in order for Exec Shield to take effect.

- **hostname** — Configures the system hostname, such as `www.example.com`.

- **hotplug** — Configures the utility to be used when a configuration change is detected by the system. This is primarily used with USB and Cardbus PCI. The default value of `/sbin/hotplug` should not be changed unless testing a new program to fulfill this role.

- **modprobe** — Sets the location of the program used to load kernel modules. The default value is `/sbin/modprobe` which means `kmod` calls it to load the module when a kernel thread calls `kmod`.

- **msgmax** — Sets the maximum size of any message sent from one process to another and is set to 8192 bytes by default. Be careful when raising this value, as queued messages between processes are stored in non-swappable kernel memory. Any increase in `msgmax` would increase RAM requirements for the system.

- **msgmnb** — Sets the maximum number of bytes in a single message queue. The default is 16384.

- **msgmni** — Sets the maximum number of message queue identifiers. The default is 4008.

- **osrelease** — Lists the Linux kernel release number. This file can only be altered by changing the kernel source and recompiling.

- **ostype** — Displays the type of operating system. By default, this file is set to `Linux`, and this value can only be changed by changing the kernel source and recompiling.
• **overflowgid** and **overflowuid** — Defines the fixed group ID and user ID, respectively, for use with system calls on architectures that only support 16-bit group and user IDs.

• **panic** — Defines the number of seconds the kernel postpones rebooting when the system experiences a kernel panic. By default, the value is set to 0, which disables automatic rebooting after a panic.

• **printk** — This file controls a variety of settings related to printing or logging error messages. Each error message reported by the kernel has a loglevel associated with it that defines the importance of the message. The loglevel values break down in this order:
  
  • 0 — Kernel emergency. The system is unusable.
  • 1 — Kernel alert. Action must be taken immediately.
  • 2 — Condition of the kernel is considered critical.
  • 3 — General kernel error condition.
  • 4 — General kernel warning condition.
  • 5 — Kernel notice of a normal but significant condition.
  • 6 — Kernel informational message.
  • 7 — Kernel debug-level messages.

Four values are found in the **printk** file:

```
6  4  1  7
```

Each of these values defines a different rule for dealing with error messages. The first value, called the console loglevel, defines the lowest priority of messages printed to the console. (Note that, the lower the priority, the higher the loglevel number.) The second value sets the default loglevel for messages without an explicit loglevel attached to them. The third value sets the lowest possible loglevel configuration for the console loglevel. The last value sets the default value for the console loglevel.

• **random/** directory — Lists a number of values related to generating random numbers for the kernel.

• **sem** — Configures semaphore settings within the kernel. A semaphore is a System V IPC object that is used to control utilization of a particular process.

• **shmall** — Sets the total amount of shared memory that can be used at one time on the system, in bytes. By default, this value is 2097152.

• **shmmmax** — Sets the largest shared memory segment size allowed by the kernel, in bytes. By default, this value is 33554432. However, the kernel supports much larger values than this.

• **shmmni** — Sets the maximum number of shared memory segments for the whole system, in bytes. By default, this value is 4096

• **sysrq** — Activates the System Request Key, if this value is set to anything other than zero (0), the default.
Chapter 19. The proc File System

The System Request Key allows immediate input to the kernel through simple key combinations. For example, the System Request Key can be used to immediately shut down or restart a system, sync all mounted file systems, or dump important information to the console. To initiate a System Request Key, type \texttt{Alt+SysRq+ system request code}. Replace \texttt{system request code} with one of the following system request codes:

- \texttt{r} — Disables raw mode for the keyboard and sets it to XLATE (a limited keyboard mode which does not recognize modifiers such as \texttt{Alt}, \texttt{Ctrl}, or \texttt{Shift} for all keys).

- \texttt{k} — Kills all processes active in a virtual console. Also called Secure Access Key (SAK), it is often used to verify that the login prompt is spawned from \texttt{init} and not a trojan copy designed to capture usernames and passwords.

- \texttt{b} — Reboots the kernel without first unmounting file systems or syncing disks attached to the system.

- \texttt{c} — Crashes the system without first unmounting file systems or syncing disks attached to the system.

- \texttt{o} — Shuts off the system.

- \texttt{s} — Attempts to sync disks attached to the system.

- \texttt{u} — Attempts to unmount and remount all file systems as read-only.

- \texttt{p} — Outputs all flags and registers to the console.

- \texttt{t} — Outputs a list of processes to the console.

- \texttt{m} — Outputs memory statistics to the console.

- \texttt{0} through \texttt{9} — Sets the log level for the console.

- \texttt{e} — Kills all processes except \texttt{init} using SIGTERM.

- \texttt{i} — Kills all processes except \texttt{init} using SIGKILL.

- \texttt{l} — Kills all processes using SIGKILL (including \texttt{init}). \textit{The system is unusable after issuing this System Request Key code.}

- \texttt{h} — Displays help text.

This feature is most beneficial when using a development kernel or when experiencing system freezes.

\begin{center}
\textbf{Caution}
\end{center}

The System Request Key feature is considered a security risk because an unattended console provides an attacker with access to the system. For this reason, it is turned off by default.

Refer to \texttt{/usr/share/doc/kernel-doc-kernel_version/Documentation/sysrq.txt} for more information about the System Request Key.

- \texttt{tainted} — Indicates whether a non-GPL module is loaded.
• 0 — No non-GPL modules are loaded.
• 1 — At least one module without a GPL license (including modules with no license) is loaded.
• 2 — At least one module was force-loaded with the command `insmod -f`.

**threads-max** — Sets the maximum number of threads to be used by the kernel, with a default value of 2048.

**version** — Displays the date and time the kernel was last compiled. The first field in this file, such as #3, relates to the number of times a kernel was built from the source base.

### 19.3.9.4. `/proc/sys/net/`

This directory contains subdirectories concerning various networking topics. Various configurations at the time of kernel compilation make different directories available here, such as `ethernet/`, `ipv4/`, `ipx/`, and `ipv6/`. By altering the files within these directories, system administrators are able to adjust the network configuration on a running system.

Given the wide variety of possible networking options available with Linux, only the most common `/proc/sys/net/` directories are discussed.

The `/proc/sys/net/core/` directory contains a variety of settings that control the interaction between the kernel and networking layers. The most important of these files are:

• **message_burst** — Sets the amount of time in tenths of a second required to write a new warning message. This setting is used to mitigate Denial of Service (DoS) attacks. The default setting is 10.

• **message_cost** — Sets a cost on every warning message. The higher the value of this file (default of 5), the more likely the warning message is ignored. This setting is used to mitigate DoS attacks. The idea of a DoS attack is to bombard the targeted system with requests that generate errors and fill up disk partitions with log files or require all of the system's resources to handle the error logging. The settings in `message_burst` and `message_cost` are designed to be modified based on the system's acceptable risk versus the need for comprehensive logging.

• **netdev_max_backlog** — Sets the maximum number of packets allowed to queue when a particular interface receives packets faster than the kernel can process them. The default value for this file is 1000.

• **optmem_max** — Configures the maximum ancillary buffer size allowed per socket.

• **rmem_default** — Sets the receive socket buffer default size in bytes.

• **rmem_max** — Sets the receive socket buffer maximum size in bytes.

• **wmem_default** — Sets the send socket buffer default size in bytes.

• **wmem_max** — Sets the send socket buffer maximum size in bytes.

The `/proc/sys/net/ipv4/` directory contains additional networking settings. Many of these settings, used in conjunction with one another, are useful in preventing attacks on the system or when using the system to act as a router.
Chapter 19. The proc File System

The following is a list of some of the more important files within the /proc/sys/net/ipv4/ directory:

- **icmp_echo_ignore_all** and **icmp_echo_ignore_broadcasts** — Allows the kernel to ignore ICMP ECHO packets from every host or only those originating from broadcast and multicast addresses, respectively. A value of 0 allows the kernel to respond, while a value of 1 ignores the packets.

- **ip_default_ttl** — Sets the default Time To Live (TTL), which limits the number of hops a packet may make before reaching its destination. Increasing this value can diminish system performance.

- **ip_forward** — Permits interfaces on the system to forward packets to one other. By default, this file is set to 0. Setting this file to 1 enables network packet forwarding.

- **ip_local_port_range** — Specifies the range of ports to be used by TCP or UDP when a local port is needed. The first number is the lowest port to be used and the second number specifies the highest port. Any systems that expect to require more ports than the default 1024 to 4999 should use a range from 32768 to 61000.

- **tcp_syn_retries** — Provides a limit on the number of times the system re-transmits a SYN packet when attempting to make a connection.

- **tcp_retries1** — Sets the number of permitted re-transmissions attempting to answer an incoming connection. Default of 3.

- **tcp_retries2** — Sets the number of permitted re-transmissions of TCP packets. Default of 15.

The file called

```
/usr/share/doc/kernel-doc-kernel_version/Documentation/networking/ip-sysct1.txt
```

contains a complete list of files and options available in the /proc/sys/net/ipv4/ directory.

A number of other directories exist within the /proc/sys/net/ipv4/ directory and each covers a different aspect of the network stack. The /proc/sys/net/ipv4/conf/ directory allows each system interface to be configured in different ways, including the use of default settings for unconfigured devices (in the /proc/sys/net/ipv4/conf/default/ subdirectory) and settings that override all special configurations (in the /proc/sys/net/ipv4/conf/all/ subdirectory).

The /proc/sys/net/ipv4/neigh/ directory contains settings for communicating with a host directly connected to the system (called a network neighbor) and also contains different settings for systems more than one hop away.

Routing over IPV4 also has its own directory, /proc/sys/net/ipv4/route/. Unlike conf/ and neigh/, the /proc/sys/net/ipv4/route/ directory contains specifications that apply to routing with any interfaces on the system. Many of these settings, such as max_size, max_delay, and min_delay, relate to controlling the size of the routing cache. To clear the routing cache, write any value to the flush file.

Additional information about these directories and the possible values for their configuration files can be found in:
19.3.9.5. /proc/sys/vm/
This directory facilitates the configuration of the Linux kernel's virtual memory (VM) subsystem. The kernel makes extensive and intelligent use of virtual memory, which is commonly referred to as swap space.

The following files are commonly found in the /proc/sys/vm/ directory:

- **block_dump** — Configures block I/O debugging when enabled. All read/write and block dirtying operations done to files are logged accordingly. This can be useful if diagnosing disk spin up and spin downs for laptop battery conservation. All output when block_dump is enabled can be retrieved via dmesg. The default value is 0.

  **Tip**

  If block_dump is enabled at the same time as kernel debugging, it is prudent to stop the klogd daemon, as it generates erroneous disk activity caused by block_dump.

- **dirty_background_ratio** — Starts background writeback of dirty data at this percentage of total memory, via a pdflush daemon. The default value is 10.

- **dirty_expire_centisecs** — Defines when dirty in-memory data is old enough to be eligible for writeout. Data which has been dirty in-memory for longer than this interval is written out next time a pdflush daemon wakes up. The default value is 3000, expressed in hundredths of a second.

- **dirty_ratio** — Starts active writeback of dirty data at this percentage of total memory for the generator of dirty data, via pdflush. The default value is 20.

- **dirty_writeback_centisecs** — Defines the interval between pdflush daemon wakeups, which periodically writes dirty in-memory data out to disk. The default value is 500, expressed in hundredths of a second.

- **laptop_mode** — Minimizes the number of times that a hard disk needs to spin up by keeping the disk spun down for as long as possible, therefore conserving battery power on laptops. This increases efficiency by combining all future I/O processes together, reducing the frequency of spin ups. The default value is 0, but is automatically enabled in case a battery on a laptop is used.

  This value is controlled automatically by the acpid daemon once a user is notified battery power is enabled. No user modifications or interactions are necessary if the laptop supports the ACPI (Advanced Configuration and Power Interface) specification.

  For more information, refer to the following installed documentation:

  /usr/share/doc/kernel-doc-kernel_version/Documentation/laptop-mode.txt

- **max_map_count** — Configures the maximum number of memory map areas a process may have. In most cases, the default value of 65536 is appropriate.
Chapter 19. The proc File System

• **min_free_kbytes** — Forces the Linux VM (virtual memory manager) to keep a minimum number of kilobytes free. The VM uses this number to compute a `pages_min` value for each `lowmem` zone in the system. The default value is in respect to the total memory on the machine.

• **nr_hugepages** — Indicates the current number of configured `hugetlb` pages in the kernel. For more information, refer to the following installed documentation:

  /usr/share/doc/kernel-doc-kernel_version/Documentation/vm/hugetlbpage.txt

• **nr_pdflush_threads** — Indicates the number of pdflush daemons that are currently running. This file is read-only, and should not be changed by the user. Under heavy I/O loads, the default value of two is increased by the kernel.

• **overcommit_memory** — Configures the conditions under which a large memory request is accepted or denied. The following three modes are available:

  • **0** — The kernel performs heuristic memory over commit handling by estimating the amount of memory available and failing requests that are blatantly invalid. Unfortunately, since memory is allocated using a heuristic rather than a precise algorithm, this setting can sometimes allow available memory on the system to be overloaded. This is the default setting.

  • **1** — The kernel performs no memory over commit handling. Under this setting, the potential for memory overload is increased, but so is performance for memory intensive tasks (such as those executed by some scientific software).

  • **2** — The kernel fails requests for memory that add up to all of swap plus the percent of physical RAM specified in `/proc/sys/vm/overcommit_ratio`. This setting is best for those who desire less risk of memory overcommitment.

        Note

This setting is only recommended for systems with swap areas larger than physical memory.

• **overcommit_ratio** — Specifies the percentage of physical RAM considered when `/proc/sys/vm/overcommit_memory` is set to 2. The default value is 50.

• **page-cluster** — Sets the number of pages read in a single attempt. The default value of 3, which actually relates to 16 pages, is appropriate for most systems.

• **swappiness** — Determines how much a machine should swap. The higher the value, the more swapping occurs. The default value, as a percentage, is set to 60.

All kernel-based documentation can be found in the following locally installed location:

19.3.10. /proc/sysvipc/

This directory contains information about System V IPC resources. The files in this directory relate to System V IPC calls for messages (`msg`), semaphores (`sem`), and shared memory (`shm`).

338
19.3.11. /proc/tty/

This directory contains information about the available and currently used tty devices on the system. Originally called teletype devices, any character-based data terminals are called tty devices.

In Linux, there are three different kinds of tty devices. Serial devices are used with serial connections, such as over a modem or using a serial cable. Virtual terminals create the common console connection, such as the virtual consoles available when pressing Alt+<F-key> at the system console. Pseudo terminals create a two-way communication that is used by some higher level applications, such as XFree86. The drivers file is a list of the current tty devices in use, as in the following example:

<table>
<thead>
<tr>
<th>Device</th>
<th>Type</th>
<th>Major</th>
<th>Min-Max</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>serial</td>
<td>/dev/cua</td>
<td>5</td>

<td>0</td>
<td>system:/dev/tty</td>
</tr>
<tr>
<td>unknown</td>
<td>/dev/vc/%d</td>
<td>4</td>
<td>1-63</td>
<td>console</td>
</tr>
</tbody>
</table>

The /proc/tty/driver/serial file lists the usage statistics and status of each of the serial tty lines.

In order for tty devices to be used as network devices, the Linux kernel enforces line discipline on the device. This allows the driver to place a specific type of header with every block of data transmitted over the device, making it possible for the remote end of the connection to recognize a block of data as just one in a stream of data blocks. SLIP and PPP are common line disciplines, and each are commonly used to connect systems to one other over a serial link.

19.3.12. /proc/PID/

Out of Memory (OOM) refers to a computing state where all available memory, including swap space, has been allocated. When this situation occurs, it will cause the system to panic and stop functioning as expected. There is a switch that controls OOM behavior in /proc/sys/vm/panic_on_oom.

When set to 1 the kernel will panic on OOM. A setting of 0 instructs the kernel to call a function named oom_killer on an OOM. Usually, oom_killer can kill rogue processes and the system will survive.

The easiest way to change this is to echo the new value to /proc/sys/vm/panic_on_oom.

```
# cat /proc/sys/vm/panic_on_oom
1

# echo 0 > /proc/sys/vm/panic_on_oom

# cat /proc/sys/vm/panic_on_oom
0
```

It is also possible to prioritize which processes get killed by adjusting the oom_killer score. In /proc/PID/ there are two tools labelled oom_adj and oom_score. Valid scores for oom_adj are in the range -16 to +15. To see the current oom_killer score, view the oom_score for the process. oom_killer will kill processes with the highest scores first.
Chapter 19. The proc File System

This example adjusts the oom_score of a process with a PID of 12465 to make it less likely that oom_killer will kill it.

```bash
# cat /proc/12465/oom_score
79872
# echo -5 > /proc/12465/oom_adj
# cat /proc/12465/oom_score
78
```

There is also a special value of -17, which disables oom_killer for that process. In the example below, oom_score returns a value of 0, indicating that this process would not be killed.

```bash
# cat /proc/12465/oom_score
78
# echo -17 > /proc/12465/oom_adj
# cat /proc/12465/oom_score
0
```

A function called badness() is used to determine the actual score for each process. This is done by adding up 'points' for each examined process. The process scoring is done in the following way:

1. The basis of each process's score is its memory size.
2. The memory size of any of the process's children (not including a kernel thread) is also added to the score.
3. The process's score is increased for 'niced' processes and decreased for long running processes.
4. Processes with the CAP_SYS_ADMIN and CAP_SYS_RAWIO capabilities have their scores reduced.
5. The final score is then bitshifted by the value saved in the oom_adj file.

Thus, a process with the highest oom_score value will most probably be a non-privileged, recently started process that, along with its children, uses a large amount of memory, has been 'niced', and handles no raw I/O.

19.4. Using the sysct1 Command

The /sbin/sysctl command is used to view, set, and automate kernel settings in the /proc/sys/ directory.

For a quick overview of all settings configurable in the /proc/sys/ directory, type the /sbin/sysctl -a command as root. This creates a large, comprehensive list, a small portion of which looks something like the following:

```
net.ipv4.route.min_delay = 2
kernel.sysrq = 0
kernel.sem = 250 32000 32 128
```

This is the same information seen if each of the files were viewed individually. The only difference is the file location. For example, the /proc/sys/net/ipv4/route/min_delay file is listed as
net.ipv4.route.min_delay, with the directory slashes replaced by dots and the proc.sys portion assumed.

The `sysctl` command can be used in place of `echo` to assign values to writable files in the `/proc/sys/` directory. For example, instead of using the command

```bash
echo 1 > /proc/sys/kernel/sysrq
```

use the equivalent `sysctl` command as follows:

```bash
sysctl -w kernel.sysrq="1"
```

While quickly setting single values like this in `/proc/sys/` is helpful during testing, this method does not work as well on a production system as special settings within `/proc/sys/` are lost when the machine is rebooted. To preserve custom settings, add them to the `/etc/sysctl.conf` file.

Each time the system boots, the `init` program runs the `/etc/rc.d/rc.sysinit` script. This script contains a command to execute `sysctl` using `/etc/sysctl.conf` to determine the values passed to the kernel. Any values added to `/etc/sysctl.conf` therefore take effect each time the system boots.

### 19.5. References

Below are additional sources of information about proc file system.

**Installed Documentation**

Some of the best documentation about the proc file system is installed on the system by default.

- `/usr/share/doc/kernel-doc-kernel_version/Documentation/filesystems/proc.txt` — Contains assorted, but limited, information about all aspects of the `/proc/` directory.

- `/usr/share/doc/kernel-doc-kernel_version/Documentation/sysctl/` — A directory containing a variety of `sysctl` tips, including modifying values that concern the kernel (`kernel.txt`), accessing file systems (`fs.txt`), and virtual memory use (`vm.txt`).

**Useful Websites**

- `http://www.linuxhq.com/` — This website maintains a complete database of source, patches, and documentation for various versions of the Linux kernel.
Part IV. System Monitoring

System administrators also monitor system performance. Red Hat Enterprise Linux contains tools to assist administrators with these tasks.
Chapter 20.

Gathering System Information

Before you learn how to configure your system, you should learn how to gather essential system information. For example, you should know how to find the amount of free memory, the amount of available hard drive space, how your hard drive is partitioned, and what processes are running. This chapter discusses how to retrieve this type of information from your Red Hat Enterprise Linux system using simple commands and a few simple programs.

20.1. System Processes

The `ps ax` command displays a list of current system processes, including processes owned by other users. To display the owner alongside each process, use the `ps aux` command. This list is a static list; in other words, it is a snapshot of what was running when you invoked the command. If you want a constantly updated list of running processes, use `top` as described below.

The `ps` output can be long. To prevent it from scrolling off the screen, you can pipe it through less:

```
ps aux | less
```

You can use the `ps` command in combination with the `grep` command to see if a process is running. For example, to determine if **Emacs** is running, use the following command:

```
ps ax | grep emacs
```

The `top` command displays currently running processes and important information about them including their memory and CPU usage. The list is both real-time and interactive. An example of output from the `top` command is provided as follows:

```
top - 18:11:48 up 1 min,  1 user, load average: 0.68, 0.30, 0.11
Tasks: 122 total,   1 running, 121 sleeping,   0 stopped,   0 zombie
Cpu(s):  0.0%us,  0.5%sy,  0.0%ni, 93.4%id,  5.7%wa,  0.2%hi,  0.2%si,  0.0
Mem:    501924k total,   376496k used,   125428k free,    29664k buffers
Swap:  1015800k total,        0k used,  1015800k free,   189008k cached
```

```
PID USER      PR  NI  VIRT  RES  SHR S %CPU %MEM    TIME+  COMMAND
1601 root      40   0 20172 1084  920 S  0.3  0.2   0:00.08 hald-addon-sto
1998 silas     40   0 14984 1160  880 R  0.3  0.2   0:00.13 top
1 root      40 15160 1412 1156 S  0.0  0.3   0:00.96 init
2 root      40   0   0   0 3000 S  0.0  0.0   0:00.00 kthreadd
3 root      RT  0 0 0 0 S 0.0 0.0 0:00.05 migration/0
4 root      20 0 0 0 0 S 0.0 0.0 0:00.00 ksoftirqd/0
5 root      RT 0 0 0 0 S 0.0 0.0 0:00.00 watchdog/0
6 root      RT 0 0 0 0 S 0.0 0.0 0:00.04 migration/1
7 root      20 0 0 0 0 S 0.0 0.0 0:00.00 ksoftirqd/1
8 root      RT 0 0 0 0 S 0.0 0.0 0:00.00 watchdog/1
9 root      20 0 0 0 0 S 0.0 0.0 0:00.00 events/0
10 root     20 0 0 0 0 S 0.0 0.0 0:00.01 events/1
11 root     20 0 0 0 0 S 0.0 0.0 0:00.00 cpuset
12 root     20 0 0 0 0 S 0.0 0.0 0:00.00 khelper
```

To exit `top`, press the `q` key.

*Table 20.1, “Interactive top commands”* contains useful interactive commands that you can use with `top`. For more information, refer to the `top(1)` manual page.
Table 20.1. Interactive top commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Space</td>
<td>Immediately refresh the display</td>
</tr>
<tr>
<td>h</td>
<td>Display a help screen</td>
</tr>
<tr>
<td>k</td>
<td>Kill a process. You are prompted for the process ID and the signal to send to it.</td>
</tr>
<tr>
<td>n</td>
<td>Change the number of processes displayed. You are prompted to enter the number.</td>
</tr>
<tr>
<td>u</td>
<td>Sort by user.</td>
</tr>
<tr>
<td>M</td>
<td>Sort by memory usage.</td>
</tr>
<tr>
<td>P</td>
<td>Sort by CPU usage.</td>
</tr>
</tbody>
</table>

If you prefer a graphical interface for top, you can use the GNOME System Monitor. To start it from the desktop, select Applications → System Tools → System Monitor or execute `gnome-system-monitor` at a shell prompt. Select the Processes tab.

The GNOME System Monitor allows you to search for a process in the list of running processes. Using the GNOME System Monitor, you can also view all processes, your processes, or active processes.

The Edit menu item allows you to:

- Stop a process.
- Continue or start a process.
- End a processes.
- Kill a process.
- Change the priority of a selected process.
- Edit the System Monitor preferences. These include changing the interval seconds to refresh the list and selecting process fields to display in the System Monitor window.

The View menu item allows you to:

- View only active processes.
- View all processes.
- View my processes.
- View process dependencies.
- View a memory map of a selected process.
- View the files opened by the selected process.
- Refresh the list of processes.

To stop a process, select it and click End Process. Alternatively you can also stop a process by selecting it, clicking Edit on your menu and selecting Stop Process.
To sort the information by a specific column, click on the name of the column. This sorts the information by the selected column in ascending order. Click on the name of the column again to toggle the sort between ascending and descending order.

![Figure 20.1. GNOME System Monitor - Processes tab](image)

### 20.2. Memory Usage

The `free` command displays the total amount of physical memory and swap space for the system as well as the amount of memory that is used, free, shared, in kernel buffers, and cached.

<table>
<thead>
<tr>
<th>Mem:</th>
<th>total</th>
<th>used</th>
<th>free</th>
<th>shared</th>
<th>buffers</th>
<th>cached</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mem:</td>
<td>4017660</td>
<td>1619044</td>
<td>2398616</td>
<td>59864</td>
<td>637968</td>
<td></td>
</tr>
<tr>
<td>-/+ buffers/cache:</td>
<td>921212</td>
<td>3096448</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Swap:</td>
<td>3071996</td>
<td>0</td>
<td>3071996</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The command `free -m` shows the same information in megabytes, which are easier to read.

<table>
<thead>
<tr>
<th>Mem:</th>
<th>total</th>
<th>used</th>
<th>free</th>
<th>shared</th>
<th>buffers</th>
<th>cached</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mem:</td>
<td>3923</td>
<td>1569</td>
<td>2353</td>
<td>0</td>
<td>58</td>
<td>626</td>
</tr>
<tr>
<td>-/+ buffers/cache:</td>
<td>884</td>
<td>3038</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Swap:</td>
<td>2999</td>
<td>0</td>
<td>2999</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If you prefer a graphical interface for `free`, you can use the **GNOME System Monitor**. To start it from the desktop, select **Applications → System Tools → System Monitor** or execute `gnome-system-monitor` at a shell prompt. Click on the **Resources** tab.
20.3. File Systems

The `df` command reports the system's disk space usage. If you execute the command `df` at a shell prompt, the output looks similar to the following:

```
Filesystem           1K-blocks      Used   Available Use% Mounted on
/dev/mapper/volgrp1-lvroot 14127024   6868092   6541316  52% /
tmpfs                  2008828      592    2008236   1% /dev/shm
/dev/sda1               495844      65047    405197  14% /boot
/dev/mapper/luks-b20f8f7a-7f0f-4497-8de4-81bfa3e541cf 122046576  12111420 103735552  11% /home
```

By default, this utility shows the partition size in 1 kilobyte blocks and the amount of used and available disk space in kilobytes. To view the information in megabytes and gigabytes, use the command `df -h`. The `-h` argument stands for human-readable format. The output looks similar to the following:

```
Filesystem            Size  Used  Avail  Use% Mounted on
/dev/mapper/volgrp1-lvroot  14G   6.6G   6.3G  52% /
tmpfs                  2.0G   592K    2.0G   1% /dev/shm
/dev/sda1              485M    64M    396M   14% /boot
/dev/mapper/luks-b20f8f7a-7f0f-4497-8de4-81bfa3e541cf 117G    12G    99G   11% /home
```

In the list of mounted partitions, there is an entry for `/dev/shm`. This entry represents the system's virtual memory file system.

The `du` command displays the estimated amount of space being used by files in a directory. If you execute `du` at a shell prompt, the disk usage for each of the subdirectories is displayed in a list. The
grand total for the current directory and subdirectories are also shown as the last line in the list. If you do not want to see the totals for all the subdirectories, use the command `du -hs` to see only the grand total for the directory in human-readable format. Use the `du --help` command to see more options.

To view the system's partitions and disk space usage in a graphical format, use the Gnome System Monitor by clicking on Applications → System Tools → System Monitor or executing the `gnome-system-monitor` command at a shell prompt. Select the File Systems tab to view the system's partitions. The figure below illustrates the File Systems tab.

![GNOME System Monitor - File Systems tab](image)

Figure 20.3. GNOME System Monitor - File Systems tab

### 20.4. Hardware

If you are having trouble configuring your hardware or just want to know what hardware is in your system, you can use the Hardware Browser application to display the hardware that can be probed. To start the program from the desktop, select System (the main menu on the panel) > Administration > Hardware or type `hwbrowser` at a shell prompt. As shown in Figure 20.4, “Hardware Browser”, it displays your CD-ROM devices, diskette drives, hard drives and their partitions, network devices, pointing devices, system devices, and video cards. Click on the category name in the left menu, and the information is displayed.
Figure 20.4. Hardware Browser

The Device Manager application can also be used to display your system hardware. This application can be started by selecting System (the main menu on the panel) > Administration > Hardware like the Hardware Browser. To start the application from a terminal, type `hal-device-manager`. Depending on your installation preferences, the graphical menu above may start this application or the Hardware Browser when clicked. The figure below illustrates the Device Manager window.
Figure 20.5. **Device Manager**

You can also use the `lspci` command to list all PCI devices. Use the command `lspci -v` for more verbose information or `lspci -vv` for very verbose output.

For example, `lspci` can be used to determine the manufacturer, model, and memory size of a system's video card:

```
00:02.1 Display controller: Intel Corporation Mobile 4 Series Chipset Integrated Graphics Controller (rev 07)
  Subsystem: Lenovo Device 20e4
  Flags: bus master, fast devsel, latency 0
  Memory at f4200000 (64-bit, non-prefetchable) [size=1M]
```
The `lspci` is also useful to determine the network card in your system if you do not know the manufacturer or model number.

20.5. Additional Resources
To learn more about gathering system information, refer to the following resources.

20.5.1. Installed Documentation
- `ps --help` — Displays a list of options that can be used with `ps`.
- `top` manual page — Execute `man top` to learn more about `top` and its many options.
- `free` manual page — Execute `man free` to learn more about `free` and its many options.
- `df` manual page — Execute `man df` to learn more about the `df` command and its many options.
- `du` manual page — Execute `man du` to learn more about the `du` command and its many options.
- `lspci` manual page — Execute `man lspci` to learn more about the `lspci` command and its many options.
- `/proc/` directory — The contents of the `/proc/` directory can also be used to gather more detailed system information.
ABRT

21.1. Overview
ABRT is the Automatic Bug-Reporting Tool. ABRT consists of a daemon that runs silently in the background most of the time. It springs into action when an application crashes. It then collects the relevant crash data such as a core file if there is one, the crashing application’s command line parameters, and other contextual puzzle pieces of forensic utility. Finally, ABRT is capable of reporting crash data to a relevant issue tracker, such as RHTSupport. Reporting crash data to a relevant issue tracker can be configured to happen automatically at every detected crash, or crash dumps can be stored locally, reviewed, reported, and deleted manually by a user. ABRT’s various plugins analyze crash data from applications written in the C, C++ and Python language, as well as report crashes to relevant issue trackers.

The ABRT package consists of:

- `abrtd`, the system service
- `abrt-applet`, which runs in the user’s Notification Area
- `abrt-gui`, the GUI application that shows collected crash dumps and allows you to edit, report, and delete them
- `abrt-cli`, the command line interface with functionality similar to `abrt-gui`.

You can open the ABRT GUI application by clicking Applications → System Tools → Automatic Bug Reporting Tool.

A number of additional packages can be installed to provide ABRT plugins and addons. To view all the available ABRT packages, type the following command:
Chapter 21. ABRT

21.2. Installing and Running ABRT

By default, ABRT should be installed on your system, the abrtd daemon configured to run at boot time, and abrt-applet to run in the Notification Area of your desktop session.

**Note: Installing the ABRT packages**

In order to use ABRT, first ensure the abrt-desktop package is installed on your system by running, as root:

```
~$ yum install abrt-desktop
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

ABRT is typically configured to start up at boot time. You can check that the abrtd daemon is running by running the following command, as root:

```
~$ service abrtd status
abrtd (pid 1559) is running...
```

If you receive **abrtd is stopped**, you can start the abrtd service by running, as root:

```
~$ service abrtd start
Starting abrtd daemon: [ OK ]
```

You can ensure that the abrtd service initializes at startup time by running the following command, as root:

```
~$ chkconfig abrtd on
```

ABRT's applet can be started by hand by running the abrt-applet program as a normal user when logged into your desktop session, or by arranging for it to be started when the GUI session is initialized. For example, on the GNOME desktop, this can be configured in System → Preferences → Startup Applications.

The ABRT alarm icon

When a crash is detected and saved, a broadcast D-Bus message is sent about this crash. If abrt-applet is running, it receives this message and displays a red alarm icon in the Notification Area. You can open the GUI application by clicking on this icon.

Alternatively, you can open the ABRT GUI application by clicking Applications → System Tools → Automatic Bug Reporting Tool.
21.3. ABRT Plugins

ABRT offers a variety of analyzer plugins and reporter plugins. These plugins are described in the following two sections. Not all of the plugins mentioned in the following sections are installed by default. To view all available plugins, run the following command:

```bash
$ yum list all | grep abrt-plugin-*
```

21.3.1. Analyzer Plugins

These plugins serve as analyzers and crash information collectors for specific types of crashes. For example, the Kerneloops analyzer plugin checks for crashes in the kernel only. These plugins can be enabled/disabled from loading at start-up in their corresponding configuration files placed in the `/etc/abrt/plugins/` directory. The following is a list of all analyzer plugins.

Kerneloops
— Checks for crashes in the kernel and consequently collects kernel crash information. It can be enabled/disabled from loading at start-up in the `/etc/abrt/plugins/Kerneloops.conf` file.

Python
— Checks for crashes in Python programs and consequently collects the crash information. It can be enabled/disabled from loading at start-up in the `/etc/abrt/plugins/Python.conf` file.

CCpp
— Checks for crashes in C and C++ programs and consequently collects the crash information. It can be enabled/disabled from loading at start-up in the `/etc/abrt/plugins/CCpp.conf` file.

21.3.2. Reporter Plugins

These plugins gather the crash data acquired by the analyzer plugins, combine the data with any user input (such as comments about the crash, reproducibility, etc.), and provide a specific output. Each of these plugins is configurable in its corresponding configuration file placed in the `/etc/abrt/plugins/` directory or in the ABRT GUI application (for more information on reporter plugin configuration in the ABRT GUI application, refer to Section 21.3.3, “Plugin Configuration in the GUI”).

RHTSupport
— Reports crashes into the Red Hat Technical Support system. Intended for users of Red Hat Enterprise Linux.

MailX
— Sends a crash report via the `mailx` utility to a specified email address.

Report Uploader
— Uploads a tarball with crash data into a FTP/SCP server

Bugzilla
— Reports crashes into Bugzilla in the form of Bugzilla database entries.
The use of the Bugzilla plugin to report crashes into Bugzilla in the form of Bugzilla database entries is strongly discouraged. Please use the RHTSupport plugin to report crashes into the Red Hat Ticketing System instead.

Logger
— Creates a crash report and saves it to a specified local file.

21.3.3. Plugin Configuration in the GUI
You can override the system-wide plugin configuration in the `/etc/abrt/plugins/*.conf` configuration files on a per-user basis. Each of the plugins specified in section Section 21.3.2, “Reporter Plugins” can be configured in the ABRT GUI application. Open the plugins window by clicking Edit → Plugins. This window shows a list of all installed plugins. You can also view each of the plugins' details by selecting one and expanding Plugin Details. When you select one of the configurable plugins, you can click the Configure plugin button and you will be able to configure your desired plugin. If you change any of the plugins' parameters, they are saved in the Gnome keyring and will be used in the future GUI sessions.

Note
All of the `/etc/abrt/plugins/*.conf` configuration files are world readable and are meant to be used as global settings. Thus, it is not advisable to store usernames, passwords or any other sensitive data in them. The per-user settings (set in the GUI application and readable by the owner of $HOME only) are stored in the Gnome keyring or can be stored in a text file in `$HOME/.abrt/*.conf` for use in `abrt-cli`. 
The following is a list of all configuration options available for each configurable plugin in the ABRT GUI application.

RHTSupport
In the **RHTSupport plugin configuration**, you can configure the following parameters:

- **RHTSupport URL** — Specifies the RHTSupport URL where crash dumps are sent (by default, set to `https://api.access.redhat.com/rs`).
- **Login** — User login which is used to log into RHTSupport and create a RHTSupport database entry for a reported crash.
- **Password** — Password used to log into RHTSupport.

When the **SSL verify** option is checked, the SSL protocol is used when sending the data over the network.

MailX
In the **MailX plugin configuration**, you can configure the following parameters:

- **Subject** — A string that appears in the **Subject** field of a crash report email sent by **mailx** (by default, set to `[abrt] crash report`).
- **Your Email** — A string that appears in the **From** field of a crash report email.
- **Recipient's Email** — Email address of the recipient of a crash report email.

When the **Send Binary Data** option is checked, the crash report email will also contain all binary files associated with the crash in an attachment. The core dump file is also sent as an attachment.
Chapter 21. ABRT

ReportUploader

In the ReportUploader plugin configuration, you can configure the following parameters:

- **Customer** — Specifies customer's identification.
- **Ticket** — Specifies the Ticket ID number in a specific issue tracker that collects crash reports.
- **URL** — Specifies the URL of the issue tracker used to collect crash reports.
- **Retry count** — Specifies the number of retries should an upload fail.
- **Retry delay** — Specifies the number of seconds between two retries.

When the **Use encryption** option is checked, the crash report sent to the issue tracker is encrypted.

When the **Upload** option is checked, all crash reports are uploaded to the specified issue tracker. If the option is unchecked, all crash reports are saved locally.

Bugzilla

In the Bugzilla plugin configuration, you can configure the following parameters:

- **Bugzilla URL** — Specifies the Bugzilla URL where crash dumps are sent (by default, set to [https://bugzilla.redhat.com](https://bugzilla.redhat.com)).
- **Login (email)** — User login which is used to log into Bugzilla and create a Bugzilla database entry for a reported crash.
- **Password** — Password used to log into Bugzilla.

When the **SSL verify** option is checked, the SSL protocol is used when sending the data over the network.

Logger

In the Logger plugin configuration, you can configure the following parameter:

- **Logger file** — Specifies a file into which the crash reports are saved (by default, set to `/var/log/abrt.log`).

When the **Append new logs** option is checked, the Logger plugin will append new crash reports to the log file specified in the **Logger file** option. When unchecked, the new crash report always replaces the previous one.

21.4. Generating Backtraces

In order to analyze a reported crash, developers need as much detail about the crash as possible. A *stack backtrace* is an important source of information when a crash in a binary program (caught by the CCpp analyzer plugin) occurs.

ABRT is configured to generate a backtrace whenever a crash is reported through the ABRT GUI application or the ABRT command line interface.

ABRT completes the following steps to generate a backtrace:

- It examines the core dump (which consists of the recorded contents of the memory of an application at a specific time), which is saved in the crash dump directory. From this file, ABRT extracts the information about the crashed binary program and information about every loaded dynamic library.
Troubleshooting Backtrace Generation

- It queries Yum to determine which debuginfo packages correspond to all the files extracted from the crash dump. This is the first potentially slow operation. Yum may need to refresh the filelists of various repositories in order to find the correct package names. This process may take a few minutes.

- It downloads the needed debuginfo packages, and extracts and saves the debuginfo files. In order to speed up future backtrace generation, debuginfo files are cached in the /var/cache/abrt-di directory.

- It generates a backtrace using GDB (the GNU Debugger) and saves it into the crash dump directory.

You can change the following backtrace generation parameters in the /etc/abrt/plugins/CCpp.conf file:

- **Backtrace** = <yes/no> — Enables/Disables backtrace generation.

- **BacktraceRemotes** = <yes/no> — For more information about this parameter, refer to Section 21.7, "Configuring Centralized Crash Collection".

- **InstallDebugInfo** = <yes/no> — Enables/Disables the installation of debuginfo packages (useful if your network is not available or it is firewalled).

- **ReadOnlyLocalDebugInfoDirs** = /path1:/path2:... — Specifies the paths of local repositories (available, for example, through a network mount) that contain pre-downloaded debuginfo packages.

- **DebugInfoCacheMB** = 4000 — Specifies the maximum size of the cached debuginfo packages in the /var/cache/abrt-di directory.

### 21.4.1. Troubleshooting Backtrace Generation

In some cases, a long delay in the ABRT GUI application occurs after choosing a crash and pressing the Report button. In this case, open the Details in the Generating backtrace window and examine the messages.

The following is a typical output seen in the Generating backtrace window:

```
Starting the debuginfo installation
Getting list of build IDs
12 missing debuginfos, getting package list from cache
12 missing debuginfos, getting package list from repositories
Downloading 7 packages
Download 1/7: acl-debuginfo-2.2.49-6.fc13.x86_64
Unpacking: acl-debuginfo-2.2.49-6.fc13.x86_64.rpm
Caching debuginfo: /usr/lib/debug/.build-id/3d/e20df1db609bd9313b1dc440796004f95911fd.debug
Download 2/7: firefox-debuginfo-3.6.7-1.fc13.x86_64
Unpacking: firefox-debuginfo-3.6.7-1.fc13.x86_64.rpm
Caching debuginfo: /usr/lib/debug/.build-id/3d/b29c9308cb276431ce8854a2d88cf83518af6.debug
Caching debuginfo: /usr/lib/debug/.build-id/a3/86884285365c8288e4e761ec034fafaaf0daee1.debug
Download 7/7: zlib-debuginfo-1.2.3-23.fc12.x86_64
Unpacking: zlib-debuginfo-1.2.3-23.fc12.x86_64.rpm
Caching debuginfo: /usr/lib/debug/.build-id/f7/933750da80f555321576e72b375caf7a3cc875.debug
All needed debuginfos are present
```
Chapter 21. ABRT

Generating backtrace

This process is performed by the /usr/bin/abrt-debuginfo-install shell script. This script uses a temporary directory (e.g. /var/run/abrt/tmp-29177-1283344373) for its operations. Normally, this directory is removed when abrt-debuginfo-install exits.

If the debuginfo installation hangs, or is unable to download anything, you may debug the problem by editing the abrt-debuginfo-install script. Change the following parameters:

debug=false
keep_tmp=false

at the top of the script to:

ddebug=true
keep_tmp=true

The first parameter instructs abrt-debuginfo-install to be verbose, the second parameter instructs abrt-debuginfo-install to not delete the /var/run/abrt/tmp-NNN-NNN directory. You can examine the log files in this directory, they may contain useful error messages.

abrt-debuginfo-install uses yum and yumdownloader to handle the debuginfo packages. In order to quickly check that your yum configuration does not cause any problems which prevent abrt-debuginfo-install from working properly, change to the /tmp directory and run the following commands, as root:

tmp[ ]# yum --enablerepo=*debuginfo* --quiet provides /usr/bin/true
tmp[ ]# yumdownloader --enablerepo=*debuginfo* --quiet coreutils

Both of these commands should complete successfully, with no error messages. The second command should download the coreutils-*-rpm file. If any error messages appear, check your yum configuration files in the /etc/yum.repos.d/* directory and the /etc/yum/* directory. If any of these commands hang, check that you do not have another instance of yum running, and that your network connection is working properly.

21.5. Using the Command Line Interface

Crashes detected by ABRT can be viewed, reported, and deleted using the command line interface.

21.5.1. Viewing Crashes

To get a list of all crashes, simply enter abrt-cli --list or abrt-cli -l:

- ]$ abrt-cli --list
  0.
    UID        : 500
    UUID       : 784b86666026e9f43718d99bf2649f19b4f251a9
    Package    : bash-4.1.2-3.el6
    Executable : /bin/bash
    Crash Time : Tue 20 Jul 2010 03:22:52 PM CEST
    Crash Count: 2

  1.
    UID        : 500
    UUID       : 48007b98d65cca4530d99a564379e2699169239d

360
This output contains basic information for every crash. The **UID** field shows the ID of the user which ran the program that caused the crash. The **Package** field shows the name and version of the Red Hat Enterprise Linux package that contains the program, and the **Executable** field shows the location of the binary or script that crashed. The **Crash Count** field indicates how many times the same crash happened.

### 21.5.2. Reporting Crashes

To report a certain crash, enter `abrt-cli --report <UUID>` or `abrt-cli --r <UUID>`, where **UUID** is a Universally Unique Identifier of a crash from the list of crashes; to view this list, execute the `abrt-cli --list` command. You do not need to remember the exact **UUID**; either use a mouse to copy and paste it, or enter a unique prefix and press `<ENTER>`.

```
~]$ abrt-cli --report 480
<ENTER>
>> Starting report creation...
```

**ABRT** analyzes the crash and creates a report about it. This might take a while. When the report is ready, **abrt-cli** opens a text editor with the content of the report. You can see what is being reported, and you can fill in instructions on how to reproduce the crash and other comments. You should also check the backtrace, because the backtrace might be sent to a public server and viewed by anyone, depending on the plugin settings.

#### Preferred Text Editor

You can choose which text editor is used to check the reports. **abrt-cli** uses the editor defined in the **ABRT_EDITOR** environment variable. If the variable is not defined, it checks the **VISUAL** and **EDITOR** variables. If none of these variables is set, **vi** is used. You can set the preferred editor in your `.bashrc` configuration file. For example, if you prefer GNU Emacs, add the following line to the file:

```
export VISUAL=emacs
```

When you are done with the report, save your changes and close the editor. You will be asked which of the enabled **ABRT** plugins you want to use to send the report. Respond **Y** to send the report using your desired plugin or **N** to skip a plugin you wish not to use.

### 21.5.3. Deleting Crashes

If you know that you do not want to report a certain crash dump, you can delete it from the crash list. To delete a certain crash dump, enter the command: `abrt-cli --delete <UUID>`.

Note that **ABRT** performs a detection of duplicate crashes by comparing new crashes with all locally saved crashes. For a repeating crash, **ABRT** requires you to act upon it only once. However, if you delete the crash dump of that crash, the next time this specific crash occurs, **ABRT** will treat it as a new crash: **ABRT** will alert you about it, prompt you to fill in a description, and report it. This can be redundant, therefore, deleting a crash is not advisable.
Chapter 21. ABRT

21.6. Configuring ABRT

ABRT’s main configuration file is /etc/abrt/abrt.conf. ABRT plugins can be configured through their config files, located in the /etc/abrt/plugins/ directory.

After changing and saving the abrt.conf configuration file, you must restart the abrtd daemon—as root—for the new settings to take effect:

```
~]# service abrtd restart
```

The following configuration directives are currently supported in /etc/abrt/abrt.conf.

[Common] Section Directives

OpenGPGCheck = <yes/no>

Setting the OpenGPGCheck directive to yes (the default setting) tells ABRT to only analyze and handle crashes in applications provided by packages which are signed by the GPG keys whose locations are listed in the /etc/abrt/gpg_keys file. Setting OpenGPGCheck to no tells ABRT to catch crashes in all programs.

BlackList = nspluginwrapper, valgrind, strace, avant-window-navigator, [<additional_packages>]

Crashes in packages and binaries listed after the BlackList directive will not be handled by ABRT. If you want ABRT to ignore other packages and binaries, list them here separated by commas.

ProcessUnpackaged = <yes/no>

This directive tells ABRT whether to process crashes in executables that do not belong to any package.

BlackListedPaths = /usr/share/doc/*, */example*

Crashes in executables in these paths will be ignored by ABRT.

Database = SQLite3

This directive instructs ABRT to store its crash data in the SQLite3 database. Other databases are not currently supported. However, ABRT’s plugin architecture allows for future support for alternative databases.

#WatchCrashdumpArchiveDir = /var/spool/abrt-upload/

This directive is commented out by default. Enable (uncomment) it if you want abrtd to auto-unpack crashdump tarballs which appear in the specified directory — in this case /var/spool/abrt-upload/ — (for example, uploaded via ftp, scp, etc.). You must ensure that whatever directory you specify in this directive exists and is writable for abrtd. abrtd will not create it automatically.

MaxCrashReportsSize = <size_in_megabytes>

This option sets the amount of storage space, in megabytes, used by ABRT to store all crash information from all users. The default setting is 1000 MB. Once the quota specified here has been met, ABRT will continue catching crashes, and in order to make room for the new crash dumps, it will delete the oldest and largest ones.

ActionsAndReporters = SOSreport, [<additional_plugins>]

This option tells ABRT to run the specified plugin(s) immediately after a crash is detected and saved. For example, the SOSreport plugin runs the sosreport tool which adds the data collected by it to the created crash dump. You can turn this behavior off by commenting out this line. For further fine-tuning, you can add SOSreport (or any other specified plugin) to either the CCpp or Python options to make ABRT run sosreport (or any other specified plugin) after any
C and C++ or Python applications crash, respectively. For more information on various Action and Reporter plugins, refer to Section 21.3, “ABRT Plugins”

[AnalyzerActionsAndReporters] Section Directives
This section allows you to associate certain analyzer actions and reporter actions to run when ABRT catches kernel oopses or crashes in C, C++, or Python programs. The actions and reporters specified in any of the directives below will run only if you run abrt-gui or abrt-cli and report the crash that occurred. If you do not specify any actions and reporters in these directives, you will not be able to report a crash via abrt-gui or abrt-cli. The order of actions and reporters is important. Commenting out a directive, will cause ABRT not to catch the crashes associated with that directive. For example, commenting out the Kerneloops line will cause ABRT not to catch kernel oopses.

Kerneloops = RHTSupport, Logger
This directive specifies that, for kernel oopses, both the RHTSupport and Logger reporters will be run.

 CCPp = RHTSupport, Logger
This directive specifies that, when C or C++ program crashes occur, both the RHTSupport and Logger reporters will be run.

Python = RHTSupport, Logger
This directive specifies that, when Python program crashes occur, both the RHTSupport and Logger reporters will be run.

Each of these destinations’ details can be specified in the corresponding plugins/*.conf file. For example, plugins/RHTSupport.conf specifies which RHTSupport URL to use (set to https://api.access.redhat.com/rs by default), the user’s login name, password for logging in to the RHTSupport site, etc. All these options can also be configured through the abrt-gui application (for more information on plugin configuration refer to Section 21.3, “ABRT Plugins”).

[Cron] Section Directives
<time> = <action_to_run>
The [Cron] section of abrt.conf allows you to specify the exact time, or elapsed amount of time between, when ABRT should run a certain action, such as scanning for kernel oopses or performing file transfers. You can list further actions to run by appending them to the end of this section.

Example 21.1. [Cron] section of /etc/abrt/abrt.conf

```plaintext
# Which Action plugins to run repeatedly
[Cron]
# h:m - at h:m
# s - every s seconds
120 = KerneloopsScanner
#02:00 = FileTransfer
```

The format for an entry is either \(<time\_in\_seconds> = <action\_to\_run>\) or \(<hh:mm> = <action\_to\_run>\), where \(hh\) (hour) is in the range 00-23 (all hours less than 10 should be zero-filled, i.e. preceded by a 0), and \(mm\) (minute) is 00-59, zero-filled likewise.

21.7. Configuring Centralized Crash Collection
You can set up ABRT so that crash reports are collected from multiple systems and sent to a dedicated system for further processing. This is useful when an administrator does not want to log into hundreds of systems and manually check for crashes found by ABRT. In order to use this
method, you need to install the `abrt-plugin-reportuploader` plugin (``yum install abrt-plugin-reportuploader``).

The steps to configure ABRT's centralized crash collection are:

1. Complete the following steps on a dedicated system ("server system"):
   
   • Create a directory to which you want the crash reports to be uploaded to. Usually, `/var/spool/abrt-upload/` is used (the rest of the document assumes you are using `/var/spool/abrt-upload/`). Make sure this directory is writable by the `abrt` user.

   **Note**
   
   When the `abrt-desktop` package is installed, it creates a new system user and and a group, both named `abrt`. This user is used by the `abrtd` daemon for various things, for example, as the owner:group of `/var/spool/abrt/*` directories.

   • In the `/etc/abrt/abrt.conf` configuration file, set the `WatchCrashdumpArchiveDir` directive to the following:

     ```
     WatchCrashdumpArchiveDir = /var/spool/abrt-upload/
     ```

   • Determine your preferred upload mechanism; for example, FTP or SCP. For more information on how to configure SCP, refer to Section 9.3.2, “Using the `scp` Utility”.

     For security reasons, make sure that uploads can only be performed by a specific user and with a password. The rest of the document assumes that the username used for uploads is `USERNAME` and the password is `PASSWORD`. If you do not already have a suitable username which can be used to perform uploads under, you may use the `abrt` user which already exists on every system where ABRT is installed.

     It is advisable to check whether your upload method works. For more information, refer to Section 21.7.2, “Testing the Upload Method”.

   • It is advisable to check and modify the following parameters if needed:

     • The `MaxCrashReportsSize` directive (in `/etc/abrt/abrt.conf`) needs to be set to a larger value if the expected volume of crash data is larger than the default 1000 MB.

     • The `ProcessUnpackaged` directive (in `/etc/abrt/abrt.conf`) needs to be set to `yes` and the `BacktraceRemotes` (in `/etc/abrt/plugins/CCpp.conf`) needs to be set to `no` if the client system and the server system have significantly different sets of installed packages.

2. Complete the following steps on every client system which will use the central management method:

   • Modify the `/etc/abrt/plugins/ReportUploader.conf` configuration file so that the `ReportUploader` plugin knows where to copy the saved crash reports in the following way:

     ```
     Enabled = yes
     Upload = yes
     ```
Testing ABRT's Crash Detection

URL = ftp://USERNAME:PASSWORD@SERVERNAME/var/spool/abrt-upload/

- To automatically send the crash reports to the server system immediately after the crash occurs, is detected, and saved, set the `[ActionsAndReporters]` directive in the `/etc/abrt/abrt.conf` configuration file to the following:

```
ActionsAndReporters = ReportUploader
```

- # Alternatively, if user interaction is required before the crash dump is sent to the server system, set the `ReportUploader` to be a reporter plugin for a specific crash type in the `[AnalyzerActionsAndReporters]` section of the `/etc/abrt/abrt.conf` configuration file. The user will be required to run `abrt-cli` or `abrt-gui` and instruct the `abrtd` daemon to report the crash and send it to the server system. For example, if you want all crash types to use this method, edit the `[AnalyzerActionsAndReporters]` section in your `/etc/abrt/abrt.conf` configuration file in the following way:

```
Kerneloops = ReportUploader
CCpp = ReportUploader
Python = ReportUploader
```

21.7.1. Testing ABRT's Crash Detection

After completing all the steps of the configuration process, the basic setup is finished. To test that this setup works properly use the `kill -s SEGV PID` command to terminate a process on a client system. For example, start a `sleep` process and terminate it with the `kill` command in the following way:

```
~$ sleep 100 &
[1] 2823
~$ kill -s SEGV 2823
```

ABRT should detect a crash shortly after executing the `kill` command. Check that the crash was detected by ABRT on the client system (this can be checked by examining the appropriate syslog file, by running the `abrt-cli --list --full` command, or by examining the crash dump created in the `/var/spool/abrt` directory), copied to the server system, unpacked on the server system and can be seen and acted upon using `abrt-cli` or `abrt-gui` on the server system.

21.7.2. Testing the Upload Method

Test your upload method from a client system to ensure that it works. For example, upload a file using the interactive FTP client:

```
~$ ftp
ftp> open SERVERNAME
Name: USERNAME
Password: PASSWORD
ftp> cd /var/spool/abrt-upload
250 Operation successful
ftp> put TESTFILE
ftp> quit
```

Check whether `TESTFILE` appeared in the correct directory on the server system.
Part V. Kernel, Module and Driver Configuration

System administrators can learn about and customize their kernels. Red Hat Enterprise Linux contains kernel tools to assist administrators with their customizations.
Working with Kernel Modules

The Linux kernel is modular, which means it can extend its capabilities through the use of dynamically-loaded kernel modules. A Kernel module can provide:

- a device driver which adds support for new hardware; or,
- support for a file system such as btrfs or NFS.

Like the kernel itself, modules can take parameters that customize their behavior, though the default parameters work well in most cases. User-space tools can list the modules currently loaded into a running kernel; query all available modules for available parameters and module-specific information; and load or unload (remove) modules dynamically into or from a running kernel. Many of these utilities, which are provided by the module-init-tools package, take module dependencies into account when performing operations so that manual dependency-tracking is rarely necessary.

On modern systems, kernel modules are automatically loaded by various mechanisms when the conditions call for it. However, there are occasions when it is necessary to load and/or unload modules manually, such as when a module provides optional functionality, one module should be preferred over another although either could provide basic functionality, or when a module is misbehaving, among other situations.

This chapter explains how to:

- use the user-space module-init-tools package to display, query, load and unload kernel modules and their dependencies;
- set module parameters both dynamically on the command line and permanently so that you can customize the behavior of your kernel modules; and,
- load modules at boot time.

Note: Installing the module-init-tools package

In order to use the kernel module utilities described in this chapter, first ensure the module-init-tools package is installed on your system by running, as root:

```
~$ yum install module-init-tools
```

For more information on installing packages with Yum, refer to Section 1.2.2, “Installing”.

22.1. Listing Currently-Loaded Modules

You can list all kernel modules that are currently loaded into the kernel by running the `lsmod` command:

```
~$ lsmod
Module                  Size  Used by
xfs                   863635  1
exportfs                3424  1 xfs
vfat                    8216  1 vfat
fat                    43418  1 vfat
tun                     13014  2
fuse                   54749  2
ip6table_filter       2743   0
```

---

Chapter 22.
Each row of `lsmod` output specifies:

- the name of a kernel module currently loaded in memory;
- the amount of memory it uses; and,
- the sum total of processes that are using the module and other modules which depend on it, followed by a list of the names of those modules, if there are any. Using this list, you can first unload all the modules depending the module you want to unload. For more information, refer to Section 22.4, “Unloading a Module”.

Finally, note that `lsmod` output is less verbose and considerably easier to read than the content of the `/proc/modules` pseudo-file.

### 22.2. Displaying Information About a Module

You can display detailed information about a kernel module by running the `modinfo <module_name>` command.

**Module names do not end in .ko**

When entering the name of a kernel module as an argument to one of the `module-init-tools` utilities, do not append a .ko extension to the end of the name. Kernel module names do not have extensions: their corresponding files do.

For example, to display information about the `e1000e` module, which is the Intel PRO/1000 network driver, run:

```
Example 22.1. Listing information about a kernel module with lsmod

~]# modinfo e1000e
```
filename: /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/net/e1000e/e1000e.ko
version: 1.2.7-k2
license: GPL
description: Intel(R) PRO/1000 Network Driver
author: Intel Corporation, <linux.nics@intel.com>
srcversion: 93CB73D3995B501872B2982
alias: pci:v00008086d00001503sv*sd*bc*sc*i*
alias: pci:v00008086d00001502sv*sd*bc*sc*i*
alias:pci:v00008086d0000105Esv*sd*bc*sc*i*
alias:pci:v00008086d0000105Esv*sd*bc*sc*i*
depends:
vermagic: 2.6.32-71.el6.x86_64 SMP mod_unload modversions
parm: copybreak:Maximum size of packet that is copied to a new buffer on receive (uint)
parm: TxIntDelay:Transmit Interrupt Delay (array of int)
parm: TxAbsIntDelay:Transmit Absolute Interrupt Delay (array of int)
parm: RxIntDelay:Receive Interrupt Delay (array of int)
parm: RxAbsIntDelay:Receive Absolute Interrupt Delay (array of int)
parm: InterruptThrottleRate:Interrupt Throttling Rate (array of int)
parm: IntMode:Interrupt Mode (array of int)
parm: SmartPowerDownEnable:Enable PHY smart power down (array of int)
parm: KumeranLockLoss:Enable Kumeran lock loss workaround (array of int)
parm: WriteProtectNVM:Write-protect NVM [WARNING: disabling this can lead to corrupted NVM] (array of int)
parm: CrcStripping:Enable CRC Stripping, disable if your BMC needs the CRC (array of int)
parm: EEE:Enable/disable on parts that support the feature (array of int)

Here are descriptions of a few of the fields in modinfo output:

filename
The absolute path to the .ko kernel object file. You can use modinfo -n as a shortcut command for printing only the filename field.

description
A short description of the module. You can use modinfo -d as a shortcut command for printing only the description field.

alias
The alias field appears as many times as there are aliases for a module, or is omitted entirely if there are none.

depends
This field contains a comma-separated list of all the modules this module depends on.

Note
If a module has no dependencies, the depends field may be omitted from the output.

parm
Each parm field presents one module parameter in the form parameter_name: description, where:

- parameter_name is the exact syntax you should use when using it as a module parameter on the command line, or in an option line in a .conf file in the /etc/modprobe.d/ directory; and,
Chapter 22. Working with Kernel Modules

- **description** is a brief explanation of what the parameter does, along with an expectation for the type of value the parameter accepts (such as int, unit or array of int) in parentheses.

You can list all parameters that the module supports by using the `-p` option. However, because useful value type information is omitted from `modinfo -p` output, it is more useful to run:

```bash
~]# modinfo e1000e |grep "^parm" |sort
parm:           copybreak:Maximum size of packet that is copied to a new buffer on receive (uint)
parm:           CrcStripping:Enable CRC Stripping, disable if your BMC needs the CRC (array of int)
parm:           EEE:Enable/disable on parts that support the feature (array of int)
parm:           InterruptThrottleRate:Interrupt Throttling Rate (array of int)
parm:           IntMode:Interrupt Mode (array of int)
parm:           KumeranLockLoss:Enable Kumeran lock loss workaround (array of int)
parm:           RxAbsIntDelay:Receive Absolute Interrupt Delay (array of int)
parm:           RxIntDelay:Receive Interrupt Delay (array of int)
parm:           SmartPowerDownEnable:Enable PHY smart power down (array of int)
parm:           TxAbsIntDelay:Transmit Absolute Interrupt Delay (array of int)
parm:           TxIntDelay:Transmit Interrupt Delay (array of int)
parm:           WriteProtectNVM:Write-protect NVM [WARNING: disabling this can lead to corrupted NVM] (array of int)
```

### 22.3. Loading a Module

To load a kernel module, run `modprobe <module_name>` as root. For example, to load the `wacom` module, run:

```bash
~]# modprobe wacom
```

By default, `modprobe` attempts to load the module from `/lib/modules/<kernel_version>/kernel/drivers/`. In this directory, each type of module has its own subdirectory, such as `net/` and `scsi/`, for network and SCSI interface drivers respectively.

Some modules have dependencies, which are other kernel modules that must be loaded before the module in question can be loaded. The `modprobe` command always takes dependencies into account when performing operations. When you ask `modprobe` to load a specific kernel module, it first examines the dependencies of that module, if there are any, and loads them if they are not already loaded into the kernel. `modprobe` resolves dependencies recursively: it will load all dependencies of dependencies, and so on, if necessary, thus ensuring that all dependencies are always met.

You can use the `-v` (i.e. --verbose) option to cause `modprobe` to display detailed information about what it is doing, which may include loading module dependencies. Here's an example of loading the Fibre Channel over Ethernet module verbosely:

#### Example 22.2. `modprobe -v` shows module dependencies as they are loaded

```bash
~]# modprobe -v fcoe
insmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/scsi/scsi_tgt.ko
insmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/scsi/scsi_transport_fc.ko
insmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/scsi/libfc/libfc.ko
insmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/scsi/fcoe/libfcoe.ko
insmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/scsi/fcoe/fcoe.ko
```

**Example 22.2.** "`modprobe -v shows module dependencies as they are loaded"** shows that `modprobe` loaded the `scsi_tgt`, `scsi_transport_fc`, `libfc` and `libfcoe` modules as dependencies
before finally loading fcoe. Also note that modprobe used the more “primitive” insmod command to insert the modules into the running kernel.

Always use modprobe instead of insmod!

Although the insmod command can also be used to load kernel modules, it does not resolve dependencies. Because of this, you should always load modules using modprobe instead.

22.4. Unloading a Module

You can unload a kernel module by running modprobe -r <module_name> as root. For example, assuming that the wacom module is already loaded into the kernel, you can unload it by running:

```
[~]# modprobe -r wacom
```

However, this command will fail if a process is using:

• the wacom module,
• a module that wacom directly depends on, or,
• any module that wacom—through the dependency tree—depends on indirectly.

Refer to Section 22.1, “Listing Currently-Loaded Modules” for more information about using lsmod to obtain the names of the modules which are preventing you from unloading a certain module.

For example, if you want to unload the firewire_ohci module because (because you believe there is a bug in it that is affecting system stability, for example), your terminal session might look similar to this:

```
[~]# modinfo -F depends firewire_ohci
depends:        firewire-core
[~]# modinfo -F depends firewire_core
depends:        crc-itu-t
[~]# modinfo -F depends crc-itu-t
```

You have figured out the dependency tree (which does not branch in this example) for the loaded Firewire modules: firewire_ohci depends on firewire_core, which itself depends on crc-itu-t.

You can unload firewire_ohci using the modprobe -r -v -v <module_name> command, where -r is short for --remove and -v for --verbose:

```
[~]# modprobe -r -v firewire_ohci
rmmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/firewire/firewire-ohci.ko
rmmod /lib/modules/2.6.32-71.el6.x86_64/kernel/drivers/firewire/firewire-core.ko
rmmod /lib/modules/2.6.32-71.el6.x86_64/kernel/lib/crc-itu-t.ko
```

The output shows that modules are unloaded in the reverse order that they are loaded, given that no processes depend on any of the modules being unloaded.
Chapter 22. Working with Kernel Modules

22.5. Setting Module Parameters

Like the kernel itself, modules can also take parameters that change their behavior. Most of the time, the default ones work well, but occasionally it is necessary or desirable to set custom parameters for a module. Because parameters cannot be dynamically set for a module that is already loaded into a running kernel, there are two different methods for setting them.

1. You can unload all dependencies of the module you want to set parameters for, unload the module using `modprobe -r`, and then load it with `modprobe` along with a list of customized parameters. This method is often used when the module does not have many dependencies, or to test different combinations of parameters without making them persistent, and is the method covered in this section.

2. Alternatively, you can list the new parameters in an existing or newly-created file in the `/etc/modprobe.d/` directory. This method makes the module parameters persistent by ensuring that they are set each time the module is loaded, such as after every reboot or `modprobe` command. This method is covered in Section 22.6, "Persistent Module Loading", though the following information is a prerequisite.

You can use `modprobe` to load a kernel module with custom parameters using the following command line format:

```
~]$ modprobe <module_name> [parameter=value]
```

Here are some things to be aware of when loading a module with custom parameters on the command line:

- You can enter multiple parameters and values by separating them with spaces.

- Some module parameters expect a list of comma-separated values as their argument. When entering the list of values, do **not** insert a space after each comma, or `modprobe` will incorrectly interpret the values following spaces as additional parameters.

- The `modprobe` command silently succeeds with an exit status of 0 if:
  - it successfully loads the module, or
  - the module is already loaded into the kernel.

Thus, you must ensure that the module is not already loaded before attempting to load it with custom parameters. The `modprobe` command does not automatically reload the module, or alert you that it is already loaded.

Here are the recommended steps for setting custom parameters and then loading a kernel module. This procedure illustrates the steps using the e1000e module, which is the network driver for Intel PRO/1000 network adapters, as an example:

---

Do not use `rmmod` directly!

Although the `rmmod` command can be used to unload kernel modules, it is recommended to use `modprobe -r` instead.

---

Example 22.3. Supplying optional parameters when loading a kernel module

```
~]$ modprobe <module_name> [parameter=value]
```
Procedure 22.1. Loading a Kernel Module with Custom Parameters

1. First, ensure the module is not already loaded into the kernel:

```
~]# lsmod |grep e1000e
~]#
```

Output indicates that the module is already loaded into the kernel, in which case you must first unload it before proceeding. Refer to Section 22.4, “Unloading a Module” for instructions on safely unloading it.

2. Load the module and list all custom parameters after the module name. For example, if you wanted to load the Intel PRO/1000 network driver with the interrupt throttle rate set to 3000 interrupts per second for the first, second and third instances of the driver, and Energy Efficient Ethernet (EEE) turned on\(^1\), you would run, as root:

```
~]# modprobe e1000e InterruptThrottleRate=3000,3000,3000 EEE=1
```

This example illustrates passing multiple valued to a single parameter by separating them with commas and omitting any spaces between them.

### 22.6. Persistent Module Loading

As shown in Example 22.1, “Listing information about a kernel module with lsmod”, many kernel modules are loaded automatically at boot time. You can specify additional modules to be loaded by creating a new `<file_name>.modules` file in the `/etc/sysconfig/modules/` directory, where `<file_name>` is any descriptive name of your choice. Your `<file_name>.modules` files are treated by the system startup scripts as shell scripts, and as such should begin with an `interpreter directive` (also called a “bang line”) as their first line:

```
Example 22.4. First line of a `file_name`.modules file

#!/bin/sh
```

Additionally, the `<file_name>.modules` file should be executable. You can make it executable by running:

```
modules]# chmod +x `<file_name>.modules`
```

For example, the following `bluez-uinput.modules` script loads the uinput module:

```
Example 22.5. `/etc/sysconfig/modules/bluez-uinput.modules`

#!/bin/sh

if [ ! -c /dev/input/uinput ]; then
  exec /sbin/modprobe uinput >/dev/null 2>&1
fi
```

The if-conditional statement on the third line ensures that the `/dev/input/uinput` file does not already exist (the `!` symbol negates the condition), and, if that is the case, loads the uinput module by calling `exec /sbin/modprobe uinput`. Note that the uinput module creates the `/dev/input/uinput` file, so testing to see if that file exists serves as verification of whether the uinput module is loaded into the kernel.
Chapter 22. Working with Kernel Modules

The following `>/dev/null 2>&1` clause at the end of that line simply redirects any output to `/dev/null` so that the `modprobe` command remains quiet.

### 22.7. Specific Kernel Module Capabilities

This section explains how to enable specific kernel capabilities using various kernel modules.

#### 22.7.1. Using Multiple Ethernet Cards

It is possible to use multiple Ethernet cards on a single machine. For each card there must be an alias and, possibly, options lines for each card in a user-created `<module_name>.conf` file in the `/etc/modprobe.d/` directory.

For additional information about using multiple Ethernet cards, refer to the Linux Ethernet-HOWTO online at [http://www.redhat.com/mirrors/LDP/HOWTO/Ethernet-HOWTO.html](http://www.redhat.com/mirrors/LDP/HOWTO/Ethernet-HOWTO.html).

#### 22.7.2. Using Channel Bonding

Red Hat Enterprise Linux allows administrators to bind NICs together into a single channel using the bonding kernel module and a special network interface, called a channel bonding interface. Channel bonding enables two or more network interfaces to act as one, simultaneously increasing the bandwidth and providing redundancy.

To channel bond multiple network interfaces, the administrator must perform the following steps:

1. As root, create a new file named `<bonding>.conf` in the `/etc/modprobe.d/` directory. Note that you can name this file anything you like as long as it ends with a `.conf` extension. Insert the following line in this new file:

   ```
   alias bond<N> bonding
   ```

   Replace `<N>` with the interface number, such as 0. For each configured channel bonding interface, there must be a corresponding entry in your new `/etc/modprobe.d/<bonding>.conf` file.

2. Configure a channel bonding interface as outlined in Section 4.2.2, “Channel Bonding Interfaces”.

3. To enhance performance, adjust available module options to ascertain what combination works best. Pay particular attention to the `miimon` or `arp_interval` and the `arp_ip_target` parameters. Refer to Section 22.7.2.1, “Bonding Module Directives” for a list of available options and how to quickly determine the best ones for your bonded interface.

#### 22.7.2.1. Bonding Module Directives

It is a good idea to test which channel bonding module parameters work best for your bonded interfaces before adding them to the `BONDING_OPTS="<bonding parameters>"` directive in your bonding interface configuration file (`ifcfg-bond0` for example). Parameters to bonded interfaces can be configured without unloading (and reloading) the bonding module by manipulating files in the sysfs file system.

sysfs is a virtual file system that represents kernel objects as directories, files and symbolic links. sysfs can be used to query for information about kernel objects, and can also manipulate those objects through the use of normal file system commands. The sysfs virtual file system has a line in `/etc/fstab`, and is mounted under the `/sys/` directory. All bonding interfaces can be configured dynamically by interacting with and manipulating files under the `/sys/class/net/` directory.
After you have created a channel bonding interface file such as `ifcfg-bond0` and inserted `SLAVE=yes` and `MASTER=bond0` directives in the configuration files for each interface bonded to bond0 following the instructions in Section 4.2.2, “Channel Bonding Interfaces”, you can proceed to testing and determining the best parameters for your bonding interface.

First, bring up the bond you created by running `ifconfig bond<N> up` as root:

```
~# ifconfig bond0 up
```

If you have correctly created the `ifcfg-bond0` bonding interface file, you will be able to see `bond0` listed in the output of running `ifconfig` (without any options):

```
~# ifconfig
bond0     Link encap:Ethernet HWaddr 00:00:00:00:00:00
          UP BROADCAST RUNNING MASTER MULTICAST  MTU:1500  Metric:1
          RX packets:0 errors:0 dropped:0 overruns:0 frame:0
          TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:0
          RX bytes:0 (0.0 b)  TX bytes:0 (0.0 b)
eth0      Link encap:Ethernet  HWaddr 52:54:00:26:9E:F1
          inet addr:192.168.122.251  Bcast:192.168.122.255  Mask:255.255.255.0
          inet6 addr: fe80::5054:ff:fe26:9ef1/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
          RX packets:207 errors:0 dropped:0 overruns:0 frame:0
          TX packets:205 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:70374 (68.7 KiB)  TX bytes:25298 (24.7 KiB)
```

To view all existing bonds, even if they are not up, run:

```
~# cat /sys/class/net/bonding_masters
bond0
```

You can configure each bond individually by manipulating the files located in the `/sys/class/net/bond<N>/bonding/` directory. First, the bond you are configuring must be taken down:

```
~# ifconfig bond0 down
```

As an example, to enable MII monitoring on bond0 with a 1 second interval, you could run (as root):

```
~# echo 1000 > /sys/class/net/bond0/bonding/miimon
```

To configure bond0 for `balance-alb` mode, you could run either:

```
~# echo 6 > /sys/class/net/bond0/bonding/mode
```

...or, using the name of the mode:

```
~# echo balance-alb > /sys/class/net/bond0/bonding/mode
```

After configuring some options for the bond in question, you can bring it up and test it by running `ifconfig bond<N> up`. If you decide to change the options, take the interface down, modify its parameters using `sysfs`, bring it back up, and re-test.

Once you have determined the best set of parameters for your bond, add those parameters as a space-separated list to the `BONDING_OPTS=` directive of the `/etc/sysconfig/network-`
Chapter 22. Working with Kernel Modules

scripts/ifcfg-bond\textless N\textgreater file for the bonding interface you are configuring. Whenever that bond is brought up (for example, by the system during the boot sequence if the ONBOOT=yes directive is set), the bonding options specified in the BONDING_OPTS will take effect for that bond. For more information on configuring bonding interfaces (and BONDING_OPTS), refer to Section 4.2.2, “Channel Bonding Interfaces”.

The following list provides the names of many of the more common channel bonding parameters, along with a descriptions of what they do. For more information, refer to the brief descriptions for each parm in modinfo bonding output, or the exhaustive descriptions in the bonding.txt file in the kernel-doc package (see Section 22.8, “Additional Resources”).

Bonding Interface Parameters

\textbf{arp_interval=\textless time\_in\_milliseconds\textgreater}

Specifies (in milliseconds) how often ARP monitoring occurs.

\textbf{Important}

It is essential that both \textbf{arp\_interval} and \textbf{arp\_ip\_target} parameters are specified, or, alternatively, the \textbf{miimon} parameter is specified. Failure to do so can cause degradation of network performance in the event that a link fails.

If using this setting while in \textbf{mode=0} or \textbf{mode=1} (the two load-balancing modes), the network switch must be configured to distribute packets evenly across the NICs. For more information on how to accomplish this, refer to /usr/share/doc/kernel-doc-<kernel_version>/Documentation/networking/bonding.txt

The value is set to 0 by default, which disables it.

\textbf{arp\_ip\_target=\textless ip\_address\textgreater[,\textless ip\_address\_2\textgreater,\ldots,\textless ip\_address\_16\textgreater]}

Specifies the target IP address of ARP requests when the \textbf{arp\_interval} parameter is enabled. Up to 16 IP addresses can be specified in a comma separated list.

\textbf{arp\_validate=\textless value\textgreater}

Validate source/distribution of ARP probes; default is \textbf{none}. Other valid values are \textbf{active}, \textbf{backup}, and \textbf{all}.

\textbf{debug=\textless number\textgreater}

Enables debug messages. Possible values are:

- 0 — Debug messages are disabled. This is the default.
- 1 — Debug messages are enabled.

\textbf{downdelay=\textless time\_in\_milliseconds\textgreater}

Specifies (in milliseconds) how long to wait after link failure before disabling the link. The value must be a multiple of the value specified in the \textbf{miimon} parameter. The value is set to 0 by default, which disables it.

\textbf{lACP\_rate=\textless value\textgreater}

Specifies the rate at which link partners should transmit LACPDU packets in 802.3ad mode. Possible values are:

- \textbf{slow} or 0 — Default setting. This specifies that partners should transmit LACPDU every 30 seconds.
Using Channel Bonding

- **fast** or 1 — Specifies that partners should transmit LACPDU's every 1 second.

`miimon=<time_in_milliseconds>`

Specifies (in milliseconds) how often MII link monitoring occurs. This is useful if high availability is required because MII is used to verify that the NIC is active. To verify that the driver for a particular NIC supports the MII tool, type the following command as root:

```
~# ethtool <interface_name> | grep "Link detected:"
```

In this command, replace `<interface_name>` with the name of the device interface, such as `eth0`, not the bond interface. If MII is supported, the command returns:

```
Link detected: yes
```

If using a bonded interface for high availability, the module for each NIC must support MII. Setting the value to 0 (the default), turns this feature off. When configuring this setting, a good starting point for this parameter is 100.

**Important**

It is essential that both `arp_interval` and `arp_ip_target` parameters are specified, or, alternatively, the `miimon` parameter is specified. Failure to do so can cause degradation of network performance in the event that a link fails.

`mode=<value>`

...where `<value>` is one of:

- **balance-rr** or 0 — Sets a round-robin policy for fault tolerance and load balancing. Transmissions are received and sent out sequentially on each bonded slave interface beginning with the first one available.

- **active-backup** or 1 — Sets an active-backup policy for fault tolerance. Transmissions are received and sent out via the first available bonded slave interface. Another bonded slave interface is only used if the active bonded slave interface fails.

- **balance-xor** or 2 — Sets an XOR (exclusive-or) policy for fault tolerance and load balancing. Using this method, the interface matches up the incoming request's MAC address with the MAC address for one of the slave NICs. Once this link is established, transmissions are sent out sequentially beginning with the first available interface.

- **broadcast** or 3 — Sets a broadcast policy for fault tolerance. All transmissions are sent on all slave interfaces.

- **802.3ad** or 4 — Sets an IEEE 802.3ad dynamic link aggregation policy. Creates aggregation groups that share the same speed and duplex settings. Transmits and receives on all slaves in the active aggregator. Requires a switch that is 802.3ad compliant.

- **balance-tlb** or 5 — Sets a Transmit Load Balancing (TLB) policy for fault tolerance and load balancing. The outgoing traffic is distributed according to the current load on each slave interface. Incoming traffic is received by the current slave. If the receiving slave fails, another slave takes over the MAC address of the failed slave.
• **balance-alb** or **6** — Sets an Active Load Balancing (ALB) policy for fault tolerance and load balancing. Includes transmit and receive load balancing for IPV4 traffic. Receive load balancing is achieved through ARP negotiation.

**num_unsol_na=number**

Specifies the number of unsolicited IPv6 Neighbor Advertisements to be issued after a failover event. One unsolicited NA is issued immediately after the failover.

The valid range is 0 - 255; the default value is 1. This parameter affects only the active-backup mode.

**primary=interface_name**

Specifies the interface name, such as eth0, of the primary device. The primary device is the first of the bonding interfaces to be used and is not abandoned unless it fails. This setting is particularly useful when one NIC in the bonding interface is faster and, therefore, able to handle a bigger load.

This setting is only valid when the bonding interface is in **active-backup** mode. Refer to /usr/share/doc/kernel-doc-<kernel-version>/Documentation/networking/bonding.txt for more information.

**primary_reselect=value**

Specifies the reselection policy for the primary slave. This affects how the primary slave is chosen to become the active slave when failure of the active slave or recovery of the primary slave occurs. This parameter is designed to prevent flip-flopping between the primary slave and other slaves. Possible values are:

* **always** or **0** (default) — The primary slave becomes the active slave whenever it comes back up.
* **better** or **1** — The primary slave becomes the active slave when it comes back up, if the speed and duplex of the primary slave is better than the speed and duplex of the current active slave.
* **failure** or **2** — The primary slave becomes the active slave only if the current active slave fails and the primary slave is up.

The **primary_reselect** setting is ignored in two cases:

* If no slaves are active, the first slave to recover is made the active slave.
* When initially enslaved, the primary slave is always made the active slave.

Changing the **primary_reselect** policy via sysfs will cause an immediate selection of the best active slave according to the new policy. This may or may not result in a change of the active slave, depending upon the circumstances.

**updelay=time_inmilliseconds**

Specifies (in milliseconds) how long to wait before enabling a link. The value must be a multiple of the value specified in the **miimon** parameter. The value is set to 0 by default, which disables it.

**use_carrier=number**

Specifies whether or not **miimon** should use MII/ETHTOOL ioctls or **netif_carrier_ok()** to determine the link state. The **netif_carrier_ok()** function relies on the device driver to maintains its state with **netif_carrier_on/off**; most device drivers support this function.
The MII/ETHTOOL ioctls tools utilize a deprecated calling sequence within the kernel. However, this is still configurable in case your device driver does not support `netif_carrier_on/off`.

Valid values are:

- **1** — Default setting. Enables the use of `netif_carrier_ok()`.
- **0** — Enables the use of MII/ETHTOOL ioctls.

**Tip**

If the bonding interface insists that the link is up when it should not be, it is possible that your network device driver does not support `netif_carrier_on/off`.

\[ xmit_hash_policy=<value> \]

Selects the transmit hash policy used for slave selection in `balance-xor` and **802.3ad** modes. Possible values are:

- **0** or **layer2** — Default setting. This parameter uses the XOR of hardware MAC addresses to generate the hash. The formula used is:

\[
\text{((source_MAC_address} \text{XOR destination_MAC}) \text{MODULO slave_count})
\]

This algorithm will place all traffic to a particular network peer on the same slave, and is 802.3ad compliant.

- **1** or **layer3+4** — Uses upper layer protocol information (when available) to generate the hash. This allows for traffic to a particular network peer to span multiple slaves, although a single connection will not span multiple slaves.

The formula for unfragmented TCP and UDP packets used is:

\[
((<source_port} \text{XOR dest_port}) \text{XOR}
((<source_IP} \text{XOR dest_IP}) \text{AND 0xffff})
\text{MODULO slave_count})
\]

For fragmented TCP or UDP packets and all other IP protocol traffic, the source and destination port information is omitted. For non-IP traffic, the formula is the same as the **layer2** transmit hash policy.

This policy intends to mimic the behavior of certain switches; particularly, Cisco switches with PFC2 as well as some Foundry and IBM products.

The algorithm used by this policy is not 802.3ad compliant.

- **2** or **layer2+3** — Uses a combination of layer2 and layer3 protocol information to generate the hash.

Uses XOR of hardware MAC addresses and IP addresses to generate the hash. The formula is:

\[
((((<source_IP} \text{XOR dest_IP}) \text{AND 0xffff}) \text{XOR}
(<source_MAC} \text{XOR destination_MAC})
\text{MODULO slave_count})
\]

This algorithm will place all traffic to a particular network peer on the same slave. For non-IP traffic, the formula is the same as for the layer2 transmit hash policy.

This policy is intended to provide a more balanced distribution of traffic than layer2 alone, especially in environments where a layer3 gateway device is required to reach most destinations.

This algorithm is 802.3ad compliant.

### 22.8. Additional Resources

For more information on kernel modules and their utilities, refer to the following resources.

**Manual Page Documentation**

- **man lsmod** — The `lsmod` manual page contains usage information and explanation of all options.
- **man modinfo** — The `modinfo` manual page contains usage information and explanation of all options.
- **man modprobe** — The `modprobe` manual page contains usage information and explanation of all options.
- **man rmmod** — The `rmmod` manual page contains usage information and explanation of all options.
- **man ethtool** — The `ethtool` manual page contains usage information and explanation of all options.
- **man mii-tool** — The `mii-tool` manual page contains usage information and explanation of all options.

**Installable and External Documentation**

- `/usr/share/doc/kernel-doc-<kernel_version>/Documentation/` — This directory, which is provided by the `kernel-doc` package, contains information on the kernel, kernel modules, and their respective parameters. Before accessing the kernel documentation, you must run the following command as root:

  ```
  ~]# yum install kernel-doc
  ```

- *Linux Loadable Kernel Module HOWTO* — The *Linux Loadable Kernel Module HOWTO* from the Linux Documentation Project contains further information on working with kernel modules.
Manually Upgrading the Kernel

The Red Hat Enterprise Linux kernel is custom-built by the Red Hat Enterprise Linux kernel team to ensure its integrity and compatibility with supported hardware. Before Red Hat releases a kernel, it must first pass a rigorous set of quality assurance tests.

Red Hat Enterprise Linux kernels are packaged in the RPM format so that they are easy to upgrade and verify using the **Yum** or **PackageKit** package managers. **PackageKit** automatically queries the Red Hat Network servers and informs you of packages with available updates, including kernel packages.

This chapter is therefore *only* useful for users who need to manually update a kernel package using the **rpm** command instead of **yum**.

---

**Use Yum to Install Kernels Whenever Possible**

Whenever possible, use either the **Yum** or **PackageKit** package manager to install a new kernel because they always install a new kernel instead of replacing the current one, which could potentially leave your system unable to boot.

---

**Important**

Building a custom kernel is not supported by the Red Hat Global Services Support team, and therefore is not explored in this manual.

---

For more information on installing kernel packages with **Yum**, refer to Section 1.1.2, “Updating Packages”.

### 23.1. Overview of Kernel Packages

Red Hat Enterprise Linux contains the following kernel packages:

- **kernel** — Contains the kernel for single, multicore and multiprocessor systems.
- **kernel-debug** — Contains a kernel with numerous debugging options enabled for kernel diagnosis, at the expense of reduced performance.
- **kernel-devel** — Contains the kernel headers and makefiles sufficient to build modules against the **kernel** package.
- **kernel-debug-devel** — Contains the development version of the kernel with numerous debugging options enabled for kernel diagnosis, at the expense of reduced performance.
- **kernel-doc** — Documentation files from the kernel source. Various portions of the Linux kernel and the device drivers shipped with it are documented in these files. Installation of this package provides a reference to the options that can be passed to Linux kernel modules at load time.

By default, these files are placed in the `/usr/share/doc/kernel-doc-<kernel_version>/` directory.
Chapter 23. Manually Upgrading the Kernel

- **kernel-headers** — Includes the C header files that specify the interface between the Linux kernel and user-space libraries and programs. The header files define structures and constants that are needed for building most standard programs.

- **kernel-firmware** — Contains all of the firmware files that are required by various devices to operate.

- **perf** — This package contains supporting scripts and documentation for the perf tool shipped in each kernel image subpackage.

### 23.2. Preparing to Upgrade

Before upgrading the kernel, it is recommended that you take some precautionary steps.

First, ensure that working boot media exists for the system in case a problem occurs. If the boot loader is not configured properly to boot the new kernel, the system cannot be booted into Red Hat Enterprise Linux without working boot media.

USB media often comes in the form of flash devices sometimes called pen drives, thumb disks, or keys, or as an externally-connected hard disk device. Almost all media of this type is formatted as a VFAT file system. You can create bootable USB media on media formatted as ext2, ext3, or VFAT.

You can transfer a distribution image file or a minimal boot media image file to USB media. Make sure that sufficient free space is available on the device. Around 4 GB is required for a distribution DVD image, around 700 MB for a distribution CD image, or around 10 MB for a minimal boot media image.

You must have a copy of the **boot.iso** file from a Red Hat Enterprise Linux installation DVD, or installation CD-ROM#1, and you need a USB storage device formatted with the VFAT file system and around 16 MB of free space. The following procedure will not affect existing files on the USB storage device unless they have the same path names as the files that you copy onto it. To create USB boot media, perform the following commands as the root user:

1. Install the SYSLINUX bootloader on the USB storage device:

   ```
   ~# syslinux /dev/sdX1
   ...
   ```
   where **sdX** is the device name.

2. Create mount points for **boot.iso** and the USB storage device:

   ```
   ~# mkdir /mnt/isoboot /mnt/diskboot
   ```

3. Mount **boot.iso**:

   ```
   ~# mount -o loop boot.iso /mnt/isoboot
   ```

4. Mount the USB storage device:

   ```
   ~# mount /dev/<sdX1> /mnt/diskboot
   ```

5. Copy the **ISOLINUX** files from the **boot.iso** to the USB storage device:

   ```
   ~# cp /mnt/isoboot/isolinux/* /mnt/diskboot
   ```

6. Use the **isolinux.cfg** file from **boot.iso** as the **syslinux.cfg** file for the USB device:
7. Unmount `boot.iso` and the USB storage device:

```
~# umount /mnt/isoboot /mnt/diskboot
```

8. You should reboot the machine with the boot media and verify that you are able to boot with it before continuing.

Alternatively, on systems with a floppy drive, you can create a boot diskette by installing the `mkbootdisk` package and running the `mkbootdisk` command as root. Refer to man `mkbootdisk` man page after installing the package for usage information.

To determine which kernel packages are installed, execute the command `yum list installed "kernel-*"` at a shell prompt. The output will comprise some or all of the following packages, depending on the system's architecture, and the version numbers may differ:

```
~# yum list installed "kernel-*"
kernel.x86_64                   2.6.32-17.el6           installed
kernel-doc.noarch               2.6.32-17.el6           installed
kernel-firmware.noarch          2.6.32-17.el6           installed
kernel-headers.x86_64           2.6.32-17.el6           installed
```

From the output, determine which packages need to be download for the kernel upgrade. For a single processor system, the only required package is the `kernel` package. Refer to Section 23.1, “Overview of Kernel Packages” for descriptions of the different packages.

### 23.3. Downloading the Upgraded Kernel

There are several ways to determine if an updated kernel is available for the system.

- **Via Red Hat Network** — Download and install the kernel RPM packages. Red Hat Network can download the latest kernel, upgrade the kernel on the system, create an initial RAM disk image if needed, and configure the boot loader to boot the new kernel. For more information, refer to [http://www.redhat.com/docs/manuals/RHNnetwork/](http://www.redhat.com/docs/manuals/RHNnetwork/).

If Red Hat Network was used to download and install the updated kernel, follow the instructions in Section 23.5, “Verifying the Initial RAM Disk Image” and Section 23.6, “Verifying the Boot Loader”, only do not change the kernel to boot by default. Red Hat Network automatically changes the default kernel to the latest version. To install the kernel manually, continue to Section 23.4, “Performing the Upgrade”.

### 23.4. Performing the Upgrade

After retrieving all of the necessary packages, it is time to upgrade the existing kernel.
Important

It is strongly recommended that you keep the old kernel in case there are problems with the new kernel.

At a shell prompt, change to the directory that contains the kernel RPM packages. Use the `rpm` command with the `-i` argument to keep the old kernel. Do not use the `-U` option, since it overwrites the currently installed kernel, which creates boot loader problems. For example:

```
~]# rpm -ivh kernel-<kernel_version>.<arch>.rpm
```

The next step is to verify that the initial RAM disk image has been created. Refer to Section 23.5, “Verifying the Initial RAM Disk Image” for details.

### 23.5. Verifying the Initial RAM Disk Image

The job of the initial RAM disk image is to preload the block device modules, such as for IDE, SCSI or RAID, so that the root file system, on which those modules normally reside, can then be accessed and mounted. On Red Hat Enterprise Linux 6 systems, whenever a new kernel is installed using either the Yum, PackageKit, or RPM package manager, the Dracut utility is always called by the installation scripts to create an initramfs (initial RAM disk image).

On all architectures other than IBM® eServer™ System i™ (see Section 23.5, “Verifying the Initial RAM Disk Image and Kernel on IBM eServer System i”), you can create an initramfs by running the `dracut` command. However, you usually don't need to create an initramfs manually: this step is automatically performed if the kernel and its associated packages are installed or upgraded from RPM packages distributed by Red Hat.

You can verify that an initramfs corresponding to your current kernel version exists and is specified correctly in the `grub.conf` configuration file by following this procedure:

**Procedure 23.1. Verifying the Initial RAM Disk Image**

1. As root, list the contents in the `/boot/` directory and find the kernel (`vmlinuz-<kernel_version>`) and `initramfs-<kernel_version>` with the latest (most recent) version number:

```
~]# ls /boot/
config-2.6.32-17.el6.x86_64 lost+found
config-2.6.32-19.el6.x86_64
config-2.6.32-22.el6.x86_64
efi
grub
initramfs-2.6.32-17.el6.x86_64.img
initramfs-2.6.32-19.el6.x86_64.img
initramfs-2.6.32-22.el6.x86_64.img
initrd-2.6.32-17.el6.x86_64.img
initrd-2.6.32-19.el6.x86_64.img
initrd-2.6.32-22.el6.x86_64.img
```

**Example 23.1. Ensuring that the kernel and initramfs versions match**

```
Example 23.1, “Ensuring that the kernel and initramfs versions match” shows that:

- we have three kernels installed (or, more correctly, three kernel files are present in `/boot/`),
the latest kernel is `vmlinuz-2.6.32-22.el6.x86_64`, and

- an initramfs file matching our kernel version, `initramfs-2.6.32-22.el6.x86_64kdump.img`, also exists.

In the `/boot/` directory you may find several `initrd-<version>kdump.img` files. These are special files created by the Kdump mechanism for kernel debugging purposes, are not used to boot the system, and can safely be ignored.

2. (Optional) If your `initramfs-<kernel_version>` file does not match the version of the latest kernel in `/boot/`, or, in certain other situations, you may need to generate an initramfs file with the Dracut utility. Simply invoking `dracut` as root without options causes it to generate an initramfs file in the `/boot/` directory for the latest kernel present in that directory:

```
$ dracut
```

You must use the `--force` option if you want Dracut to overwrite an existing initramfs (for example, if your initramfs has become corrupt). Otherwise Dracut will refuse to overwrite the existing initramfs file:

```
$ dracut
Will not override existing initramfs (/boot/initramfs-2.6.32-22.el6.x86_64.img) without --force
```

You can create an initramfs in the current directory by calling `dracut <initramfs_name> <kernel_version>`:

```
$ dracut "initramfs-$(uname -r).img" ${uname -r}
```

If you need to specify specific kernel modules to be preloaded, add the names of those modules (minus any file name suffixes such as `.ko`) inside the parentheses of the `add_dracutmodules="<module> [<more_modules>]"` directive of the `/etc/dracut.conf` configuration file. You can list the file contents of an initramfs image file created by dracut by using the `lsinitrd <initramfs_file>` command:

```
$ lsinitrd
```

Refer to `man dracut` and `man dracut.conf` for more information on options and usage.
3. Examine the `grub.conf` configuration file in the `/boot/grub/` directory to ensure that an `initrd initramfs-<kernel_version>.img` exists for the kernel version you are booting. Refer to Section 23.6, “Verifying the Boot Loader” for more information.

**Verifying the Initial RAM Disk Image and Kernel on IBM eServer System i**

On IBM eSeries System i machines, the initial RAM disk and kernel files are combined into a single file, which is created with the `addRamDisk` command. This step is performed automatically if the kernel and its associated packages are installed or upgraded from the RPM packages distributed by Red Hat; thus, it does not need to be executed manually. To verify that it was created, use the command `ls -l /boot/` to make sure the `/boot/vmlinitrd-<kernel_version>` file already exists (the `<kernel_version>` should match the version of the kernel just installed).

### 23.6. Verifying the Boot Loader

When you install a kernel using `rpm`, the kernel package creates an entry in the boot loader configuration file for that new kernel. However, `rpm` does not configure the new kernel to boot as the default kernel. You must do this manually when installing a new kernel with `rpm`.

It is always recommended to double-check the boot loader configuration file after installing a new kernel with `rpm` to ensure that the configuration is correct. Otherwise, the system may not be able to boot into Red Hat Enterprise Linux properly. If this happens, boot the system with the boot media created earlier and re-configure the boot loader.

In the following table, find your system’s architecture to determine the boot loader it uses, and then click on the “Refer to” link to jump to the correct instructions for your system.

</table>

### 23.6.1. Configuring the GRUB Boot Loader

GRUB’s configuration file, `/boot/grub/grub.conf`, contains a few lines with directives, such as `default`, `timeout`, `splashimage` and `hiddenmenu` (the last directive has no argument). The remainder of the file contains 4-line stanzas that each refer to an installed kernel. These stanzas always start with a `title` entry, after which the associated `root`, `kernel` and `initrd` directives should always be indented. Ensure that each stanza starts with a `title` that contains a version number (in parentheses) that matches the version number in the `kernel / vmlinuz-<version_number>` line of the same stanza.
If a separate /boot/ partition was created, the paths to the kernel and the initramfs image are relative to /boot/. This is the case in Example 23.2, "/boot/grub/grub.conf", above. Therefore the `initrd /initramfs-2.6.32-22.el6.x86_64.img` line in the first kernel stanza means that the initramfs image is actually located at /boot/initramfs-2.6.32-22.el6.x86_64.img when the root file system is mounted, and likewise for the kernel path (for example: `kernel /vmlinuz-2.6.32-22.el6.x86_64`) in each stanza of grub.conf. 

The initrd directive in grub.conf refers to an initramfs image

In kernel boot stanzas in grub.conf, the `initrd` directive must point to the location (relative to the /boot/ directory if it is on a separate partition), of the `initramfs` file corresponding to the same kernel version. This directive is called `initrd` because the previous tool which created initial RAM disk images, mkinitrd, created what were known as `initrd` files. Thus the `grub.conf` directive remains `initrd` to maintain compatibility with other tools. The file-naming convention of systems using the `dracut` utility to create the initial RAM disk image is: `initramfs-<kernel_version>.img`

`Dracut` is a new utility available in Red Hat Enterprise Linux 6, and much-improved over `mkinitrd`. For information on using `Dracut`, refer to Section 23.5, "Verifying the Initial RAM Disk Image".

You should ensure that the kernel version number as given on the `kernel /vmlinuz-<kernel_version>` line matches the version number of the initramfs image given on the `initrd /initramfs-<kernel_version>.img` line of each stanza. Refer to Procedure 23.1, "Verifying the Initial RAM Disk Image" for more information.
Chapter 23. Manually Upgrading the Kernel

The `default=` directive tells GRUB which kernel to boot by default. Each `title` in `grub.conf` represents a bootable kernel. GRUB counts the `title` stanzas representing bootable kernels starting with 0. In Example 23.2, `/boot/grub/grub.conf`, the line `default=1` indicates that GRUB will boot, by default, the second kernel entry, i.e. `title Red Hat Enterprise Linux (2.6.32-19.el6.x86_64)`.

In Example 23.2, `/boot/grub/grub.conf` GRUB is therefore configured to boot an older kernel, when we compare by version numbers. In order to boot the newer kernel, which is the first `title` entry in `grub.conf`, we would need to change the `default` value to 0.

After installing a new kernel with `rpm`, verify that `/boot/grub/grub.conf` is correct, change the `default=` value to the new kernel (while remembering to count from 0), and reboot the computer into the new kernel. Ensure your hardware is detected by watching the boot process output.

If GRUB presents an error and is unable to boot into the default kernel, it is often easiest to try to boot into an alternative or older kernel so that you can fix the problem.

### Important: Causing the GRUB boot menu to display

If you set the `timeout` directive in `grub.conf` to 0, GRUB will not display its list of bootable kernels when the system starts up. In order to display this list when booting, press and hold any alphanumeric key while and immediately after BIOS information is displayed, and GRUB will present you with the GRUB menu.

Alternatively, use the boot media you created earlier to boot the system.

#### 23.6.2. Configuring the OS/400® Boot Loader

The `/boot/vmlinitrd-<kernel-version>` file is installed when you upgrade the kernel. However, you must use the `dd` command to configure the system to boot the new kernel.

1. As root, issue the command `cat /proc/iSeries/mf/side` to determine the default side (either A, B, or C).

2. As root, issue the following command, where `<kernel-version>` is the version of the new kernel and `<side>` is the side from the previous command:

   ```
   dd if=/boot/vmlinitrd-<kernel-version> of=/proc/iSeries/mf/<side>/vmlinux bs=8k
   ```

Begin testing the new kernel by rebooting the computer and watching the messages to ensure that the hardware is detected properly.

#### 23.6.3. Configuring the YABOOT Boot Loader

IBM eServer System p uses YABOOT as its boot loader. YABOOT uses `/etc/aboot.conf` as its configuration file. Confirm that the file contains an `image` section with the same version as the `kernel` package just installed, and likewise for the `initramfs` image:

```
boot=/dev/sda1 init-message=Welcome to Red Hat Enterprise Linux! Hit <TAB> for boot options partition=2 timeout=30 install=/usr/lib/yaboot/yaboot delay=10 nonvram image=/vmlinuz-2.6.32-17.EL label=old read-only
```
Notice that the default is not set to the new kernel. The kernel in the first image is booted by default. To change the default kernel to boot either move its image stanza so that it is the first one listed or add the directive `default` and set it to the `label` of the image stanza that contains the new kernel.

Begin testing the new kernel by rebooting the computer and watching the messages to ensure that the hardware is detected properly.
The kdump Crash Recovery Service

kdump is an advanced crash dumping mechanism. When enabled, the system is booted from the context of another kernel. This second kernel reserves a small amount of memory, and its only purpose is to capture the core dump image in case the system crashes. Since being able to analyze the core dump helps significantly to determine the exact cause of the system failure, it is strongly recommended to have this feature enabled.

This chapter explains how to configure, test, and use the kdump service in Red Hat Enterprise Linux, and provides a brief overview of how to analyze the resulting core dump using the crash debugging utility.

24.1. Configuring the kdump Service

This section covers three common means of configuring the kdump service: at the first boot, using the Kernel Dump Configuration graphical utility, and doing so manually on the command line. It also describes how to test the configuration to verify that everything works as expected.

**Note: Make Sure You Have kexec-tools Installed**

To use the kdump service, you must have the kexec-tools package installed. Refer to Section 1.2.2, “Installing” for more information on how to install new packages in Red Hat Enterprise Linux.

24.1.1. Configuring the kdump at First Boot

When the system boots for the first time, the firstboot application is launched to guide a user through the initial configuration of the freshly installed system. To configure kdump, navigate to the Kdump section, and follow the instructions below.

**Important: Make Sure the System Has Enough Memory**

Unless the system has enough memory, this option will not be available. For the information on minimum memory requirements, refer to the Required minimums section of the Red Hat Enterprise Linux comparison chart. Note that when the kdump crash recovery is enabled, the minimum memory requirements increase by the amount of memory reserved for it. This value is determined by a user, and defaults to 128 MB.

24.1.1.1. Enabling the Service

To start the kdump daemon at boot time, select the Enable kdump? check box. This will enable the service for runlevels 2, 3, 4, and 5, and start it for the current session. Similarly, unselecting the check box will disable it for all runlevels and stop the service immediately.

24.1.1.2. Configuring the Memory Usage

To configure the amount of memory that is reserved for the kdump kernel, click the up and down arrow buttons next to the Kdump Memory field to increase or decrease the value. Notice that the Usable

---

1 http://www.redhat.com/rhel/compare/
System Memory field changes accordingly showing you the remaining memory that will be available to the system.

24.1.2. Using the Kernel Dump Configuration Utility

To start the Kernel Dump Configuration utility, select System → Administration → Kernel crash dumps from the panel, or type `system-config-kdump` at a shell prompt (for example, `xterm` or GNOME Terminal). You will be presented with a window as shown in Figure 24.1, “Basic Settings”.

The utility allows you to configure kdump as well as to enable or disable starting the service at boot time. When you are done, click Apply to save the changes. The system reboot will be requested, and unless you are already authenticated, you will be prompted to enter the superuser password.

Important: Make Sure the System Has Enough Memory

Unless the system has enough memory, the utility will not start, and you will be presented with the following error message:

This system does not have enough memory for kdump to be viable

For the information on minimum memory requirements, refer to the Required minimums section of the Red Hat Enterprise Linux comparison chart. Note that when the kdump crash recovery is enabled, the minimum memory requirements increase by the amount of memory reserved for it. This value is determined by a user, and defaults to 128 MB.

24.1.2.1. Enabling the Service

To start the kdump daemon at boot time, click the Apply button on the toolbar. This will enable the service for runlevels 2, 3, 4, and 5, and start it for the current session. Similarly, clicking the Disable button will disable it for all runlevels and stop the service immediately.

For more information on runlevels and configuring services in general, refer to Chapter 7, Controlling Access to Services.

24.1.2.2. The Basic Settings Tab

The Basic Settings tab enables you to configure the amount of memory that is reserved for the kdump kernel. To do so, select the Manual kdump memory settings radio button, and click the up and down arrow buttons next to the New kdump Memory field to increase or decrease the value. Notice that the Usable Memory field changes accordingly showing you the remaining memory that will be available to the system.

2 http://www.redhat.com/rhel/compare/
Using the Kernel Dump Configuration Utility

24.1.2.3. The Target Settings Tab

The Target Settings tab enables you to specify the target location for the vmcore dump. It can be either stored as a file in a local file system, written directly to a device, or sent over a network using the NFS (Network File System) or SSH (Secure Shell) protocol.

To save the dump to the local file system, select the Local filesystem radio button. Optionally, you can customize the settings by choosing a different partition from the Partition, and a target directory from the Path pulldown lists.

To write the dump directly to a device, select the Raw device radio button, and choose the desired target device from the pulldown list next to it.

To store the dump to a remote machine, select the Network radio button. To use the NFS protocol, select the NFS radio button, and fill the Server name and Path to directory fields. To use the SSH protocol, select the SSH radio button, and fill the Server name, Path to directory, and User name fields with the remote server address, target directory, and a valid remote user name respectively.
Refer to Chapter 9, OpenSSH for information on how to configure an SSH server, and how to set up a key-based authentication.

**Important: Using the hpsa Driver for a Storage**

Due to known issue with the hpsa driver, kdump is unable to save the dump to a storage that uses this driver for HP Smart Array Controllers. If this applies to your machine, it is advised that you save the dump to a remote system using the NFS or SSH protocol instead.

### 24.1.2.4. The Filtering Settings Tab

The **Filtering Settings** tab enables you to select the filtering level for the *vmcore* dump.

![Filtering Settings](image)

**Figure 24.3. Filtering Settings**

To exclude the zero page, cache page, cache private, user data, or free page from the dump, select the check box next to the appropriate label.

### 24.1.2.5. The Expert Settings Tab

The **Expert Settings** tab enables you to choose which kernel and initial RAM disk to use, as well as to customize the options that are passed to the kernel and the core collector program.
Configuring kdump on the Command Line

24.1.3. Configuring kdump on the Command Line

To perform actions described in this section, you have to be logged in as a superuser:

```
~]$ su -
Password:
```

24.1.3.1. Configuring the Memory Usage

To configure the amount of memory that is reserved for the kdump kernel, open the `/boot/grub/grub.conf` file in a text editor such as `vi` or `nano`, and add the `crashkernel=<size>M` parameter to the list of kernel options as shown in Example 24.1, “A sample `/boot/grub/grub.conf` file”.

Example 24.1. A sample `/boot/grub/grub.conf` file

```
# grub.conf generated by anaconda
#
# Note that you do not have to rerun grub after making changes to this file
# NOTICE: You have a /boot partition. This means that
```
Chapter 24. The kdump Crash Recovery Service

Important: Make Sure the System Has Enough Memory

When the kdump crash recovery is enabled, the minimum memory requirements increase by the amount of memory reserved for it. This value is determined by a user, and defaults to 128 MB, as lower values proved to be unreliable. For more information on minimum memory requirements for Red Hat Enterprise Linux 6, refer to the Required minimums section of the Red Hat Enterprise Linux comparison chart.

24.1.3.2. Configuring the Target Type

When a kernel crash is captured, the core dump can be either stored as a file in a local file system, written directly to a device, or sent over a network using the NFS (Network File System) or SSH (Secure Shell) protocol. Note that only one of these options can be set at the moment. The default option is to store the vmcore file in the /var/crash/ directory of the local file system. To change this, open the /etc/kdump.conf configuration file in a text editor such as vi or nano, and edit the options as described below.

To change the local directory in which the core dump is to be saved, remove the hash sign (“#”) from the beginning of the #path /var/crash line, and replace the value with a desired directory path. Optionally, if you wish to write the file to a different partition, follow the same procedure with the #ext4 /dev/sda3 line as well, and change both the file system type and the device (a device name, a file system label, and UUID are all supported) accordingly. For example:

```
ext3 /dev/sda4
path /usr/local/cores
```

To write the dump directly to a device, remove the hash sign (“#”) from the beginning of the #raw / dev/sda5 line, and replace the value with a desired device name. For example:

```
raw /dev/sdb1
```

To store the dump to a remote machine using the NFS protocol, remove the hash sign (“#”) from the beginning of the #net my.server.com:/export/tmp line, and replace the value with a valid hostname and directory path. For example:

```
et penguin.example.com:/export/cores
```
To store the dump to a remote machine using the SSH protocol, remove the hash sign (“#”) from the beginning of the `net user@my.server.com` line, and replace the value with a valid username and hostname. For example:

```
net john@penguin.example.com
```

Refer to Chapter 9, OpenSSH for information on how to configure an SSH server, and how to set up a key-based authentication.

**Important: Using the hpsa Driver for a Storage**

Due to known issue with the hpsa driver, kdump is unable to save the dump to a storage that uses this driver for HP Smart Array Controllers. If this applies to your machine, it is advised that you save the dump to a remote system using the NFS or SSH protocol instead.

### 24.1.3.3. Configuring the Core Collector

To reduce the size of the `vmcore` dump file, kdump allows you to specify an external application (that is, a core collector) to compress the data, and optionally leave out all irrelevant information. Currently, the only fully supported core collector is `makedumpfile`.

To enable the core collector, open the `/etc/kdump.conf` configuration file in a text editor such as `vi` or `nano`, remove the hash sign (“#”) from the beginning of the `#core_collector makedumpfile -c --message-level 1 -d 31` line, and edit the command line options as described below.

To enable the dump file compression, add the `-c` parameter. For example:

```
core_collector makedumpfile -c
```

To remove certain pages from the dump, add the `-d value` parameter, where `value` is a sum of values of pages you want to omit as described in Table 24.1, “Supported filtering levels”. For example, to remove both zero and free pages, use the following:

```
core_collector makedumpfile -d 17 -c
```

Refer to the manual page for `makedumpfile` for a complete list of available options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Zero pages</td>
</tr>
<tr>
<td>2</td>
<td>Cache pages</td>
</tr>
<tr>
<td>4</td>
<td>Cache private</td>
</tr>
<tr>
<td>8</td>
<td>User pages</td>
</tr>
<tr>
<td>16</td>
<td>Free pages</td>
</tr>
</tbody>
</table>

### 24.1.3.4. Changing the Default Action

By default, when the kernel crash is captured, the root file system is mounted, and `/sbin/init` is run. To change this behavior, open the `/etc/kdump.conf` configuration file in a text editor such as `vi` or `nano`, remove the hash sign (“#”) from the beginning of the `#default shell` line, and replace the value with a desired action as described in Table 24.2, “Supported actions”. For example:
default halt

Table 24.2. Supported actions

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reboot</td>
<td>Reboot the system, losing the core in the process.</td>
</tr>
<tr>
<td>halt</td>
<td>After attempting to capture a core, halt the system no matter if it succeeded.</td>
</tr>
<tr>
<td>poweroff</td>
<td>Power off the system.</td>
</tr>
<tr>
<td>shell</td>
<td>Run the msh session from within the initramfs, allowing a user to record the core manually.</td>
</tr>
</tbody>
</table>

24.1.3.5. Enabling the Service

To start the kdump daemon at boot time, type the following at a shell prompt:

```
~]# chkconfig kdump on
```

This will enable the service for runlevels 2, 3, 4, and 5. Similarly, typing `chkconfig kdump off` will disable it for all runlevels. To start the service in the current session, use the following command:

```
~]# service kdump start
```

```
No kdump initial ramdisk found.                       [WARNING]
Rebuilding /boot/initrd-2.6.32-54.el6.i686kdump.img
Starting kdump:                                          [ OK ]
```

For more information on runlevels and configuring services in general, refer to Chapter 7, Controlling Access to Services.

24.1.4. Testing the Configuration

Caution: Be Careful When Using These Commands

The commands below will cause the kernel to crash. Use caution when following these steps, and by no means use them on a production machine.

To test the configuration, reboot the system with kdump enabled, and make sure that the service is running (refer to Section 7.3, “Running the Services” for more information on how to run a service in Red Hat Enterprise Linux):

```
~]# service kdump status
Kdump is operational
```

Then type the following commands at a shell prompt:

```
~]# echo 1 > /proc/sys/kernel/sysrq
~]# echo c > /proc/sysrq-trigger
```

This will force the Linux kernel to crash, and the `address-YYYY-MM-DD-HH:MM:SS/vmcore` file will be copied to the location you have selected in the configuration (that is, to `/var/crash/` by default).
Example 24.2. Listing a content of `/var/crash/` after a crash

```
[-]# tree --charset=ascii /var/crash
/var/crash
  `-- 127.0.0.1-2010-08-25-08:45:02
    `-- vmcore
1 directory, 1 file
```

24.2. Analyzing the Core Dump

To determine the cause of the system crash, you can use the `crash` utility. This utility allows you to interactively analyze a running Linux system as well as a core dump created by `netdump`, `diskdump`, `xendump`, or `kdump`. When started, it presents you with an interactive prompt very similar to the GNU Debugger (GDB).

**Note: Make Sure You Have Relevant Packages Installed**

To analyze the `vmcore` dump file, you must have the `crash` and `kernel-debuginfo` packages installed. To do so, type the following at a shell prompt:

```
[-]# yum install --enablerepo=rhel-debuginfo crash kernel-debuginfo
```

Refer to Section 1.2.2, “Installing” for more information on how to install new packages in Red Hat Enterprise Linux.

To start the utility, type the command in the following form at a shell prompt:

```
crash /var/crash/timestamp/vmcore /usr/lib/debug/lib/modules/kernel/vmlinux
```

Note that the `kernel` version should be the same that was captured by `kdump`. To find out which kernel you are currently running, use the `uname -r` command.

Example 24.3. Running the `crash` utility

```
[-]# crash /usr/lib/debug/lib/modules/2.6.32-69.el6.i686/vmlinux \
    /var/crash/127.0.0.1-2010-08-25-08:45:02/vmcore
```

24.2.2. Displaying a Backtrace

To display the kernel stack trace, type the `bt` command at the interactive prompt. You can use `bt pid` to display the backtrace of the selected process.

Example 24.5. Displaying the kernel stack trace

```
crash> bt

```

Type `help bt` for more information on the command usage.

24.2.3. Displaying a Process Status

To display status of processes in the system, type the `ps` command at the interactive prompt. You can use `ps pid` to display the status of the selected process.

Example 24.6. Displaying status of processes in the system

```
crash> ps
            PID PPID CPU TASK       ST  %MEM  VSZ    RSS  COMM
>     0 0 0 0 c09dc560 RU  0.0 0 0 [swapper]
>     0 0 1 f7072038 RU  0.0 0 0 [swapper]
0 2 f70a3a90 RU  0.0 0 0 [swapper]
>     0 0 3 f70ac560 RU  0.0 0 0 [swapper]

```

Type `help ps` for more information on the command usage.
24.2.4. Displaying Virtual Memory Information

To display basic virtual memory information, type the `vm` command at the interactive prompt. You can use `vm pid` to display information on the selected process.

Example 24.7. Displaying virtual memory information of the current context

```
crash> vm
PID: 5591   TASK: f196d560  CPU: 2   COMMAND: "bash"
MM      PGD      RSS    TOTAL_VM
f19b5900 ef9c6000 1648k    5084k

```

Type `help vm` for more information on the command usage.

24.2.5. Displaying Open Files

To display information about open files, type the `files` command at the interactive prompt. You can use `files pid` to display files opened by the selected process.

Example 24.8. Displaying information about open files of the current context

```
crash> files
PID: 5591   TASK: f196d560  CPU: 2   COMMAND: "bash"
ROOT: /    CWD: /root
FD    FILE     DENTRY    INODE    TYPE  PATH
0  f734f640  eedc2c6c  eecd6048  CHR   /pts/0
1  efade5c0  eee14090  f00431d4  REG   /proc/sysrq-trigger
2  f734f640  eedc2c6c  eecd6048  CHR   /pts/0
10  f734f640  eedc2c6c  eecd6048  CHR   /pts/0
255 f734f640  eedc2c6c  eecd6048  CHR   /pts/0
```

Type `help files` for more information on the command usage.
24.3. Additional Resources

24.3.1. Installed Documentation

\texttt{man kdump.conf}
\par The manual page for the \texttt{/etc/kdump.conf} configuration file containing the full documentation of available options.

\texttt{man makedumpfile}
\par The manual page for the \texttt{makedumpfile} core collector containing the full documentation on its usage.

\texttt{man kexec}
\par The manual page for \texttt{kexec} containing the full documentation on its usage.

\texttt{man crash}
\par The manual page for \texttt{crash} utility containing the full documentation on its usage.

\texttt{/usr/share/doc/kexec-tools-version/kexec-kdump-howto.txt}
\par An overview of the \texttt{kdump} and \texttt{kexec} installation and usage.

24.3.2. Useful Websites

\texttt{https://access.redhat.com/kb/docs/DOC-6039}
\par The Red Hat Knowledgebase article about the \texttt{kexec} and \texttt{kdump} configuration.

\texttt{http://people.redhat.com/anderson/}
\par The \texttt{crash} utility homepage.
