

2011 VERMONT SMALL GRAIN FORAGE TRIALS

INTRODUCTION

In 2011, the University of Vermont Extension continued their research evaluating several organic annual forage models. Spring cereal grains such as oats, barley, triticale, wheat, and spelt could have the potential to provide high yield and quality feed for livestock. Spring grains are planted in mid to late April and can be harvested at various stages of development. The objective of this project was to evaluate yield and quality of spring grains harvested in the vegetative, milk, or soft dough stage. The overall goal of this project is to help organic dairy producers reduce their reliance on expensive concentrates through the production of a variety of high quality annual forages. In addition, we were interested in investigating the value of combining brassica forage with these cool season annuals.

METHODS

In 2011, an organic small grain forage trial was conducted at Borderview Research Farm in Alburgh, VT (Table 1). The farm is certified organic by Vermont Organic Farmers, LLC. The previous crop was organic corn silage. The seedbed was prepared by conventional tillage methods. Plots were planted with a six-inch grain drill on May 13, 2011. The oats, barley, spelt, and triticale were planted at 125 lbs/acre. The Barkant turnips were planted at 8 lbs/acre. The varieties and seed source are in Table 2. All plots measured 5' x 20' and were fertilized with Pro-Booster organic fertilizer at a rate of 70 lbs. N acre⁻¹ on June 28, 2011. Each treatment was harvested at three development stages, vegetative stage, milk stage, and soft dough stage. Subsamples of approximately 2.5 ft² were cut to the ground, dried at 40°C, and weighed to determine dry matter yield. Oven dry samples were coarsely ground with a Wiley mill (Thomas Scientific, Swedesboro, NJ) and sent to Cumberland Valley Analytical Services, Inc. (Hagerstown, MD) for quality analysis. Results were analyzed with an analysis of variance with SAS (Cary, NC).

Table 1 General plot management.

Trial Information	Borderview Farm, Alburgh, VT
Soil type	Benson rocky silt loam
Previous crop	Corn silage
Row width (in.)	6
Planting date	13-May
<u>Harvest dates:</u>	
Vegetative	27-June
Milk	13-July (Barley) 14-July (Wheat)
Soft Dough	25-July (Spelt, Oats, Triticale) 26-July (Barley and Wheat) 8-August (Spelt, Oats, Triticale)
Seeding rate	125 lbs/acre
Tillage methods	Mold board plow, disk, and spike tooth harrow
Fertilizer applications	ProBooster 70 lbs. N/acre on 28-June

SILAGE QUALITY

Silage quality was analyzed by Cumberland Valley Analytical Forage Laboratory in Hagerstown, Maryland. Plot samples were dried, ground and analyzed for crude protein (CP), acid detergent fiber (ADF), neutral detergent fiber (NDF), and various other nutrients. The Nonstructural Carbohydrates (NSC) and Total Digestible Nutrients (TDN) were calculated from forage analysis data. Performance indices such as Net Energy Lactation (NEL) were calculated to determine forage value. Mixtures of true proteins, composed of amino acids, and nonprotein nitrogen make up the crude protein (CP) content of forages. The bulky characteristics of forage come from fiber. Forage feeding values are negatively associated with fiber since the less digestible portions of the plant are contained in the fiber fraction. The detergent fiber analysis system separates forages into two parts: cell contents, which include sugars, starches, proteins, non-protein nitrogen, fats and other highly digestible compounds; and the less digestible components found in the fiber fraction. The total fiber content of forage is contained in the neutral detergent fiber (NDF). Chemically, this fraction includes cellulose, hemicellulose, and lignin. Recently, forage testing laboratories have begun to evaluate forages for NDF digestibility. Evaluation of forages and other feedstuffs for NDF digestibility is being conducted to aid prediction of feed energy content and animal performance. Research has demonstrated that lactating dairy cows will eat more dry matter and produce more milk when fed forages with optimum NDF digestibility. Forages with increased NDF digestibility (dNDF) will result in higher energy values, and perhaps more importantly, increased forage intakes. Forage NDF digestibility can range from 20 – 80%. The NSC or non-fiber carbohydrates (NFC) include starch, sugars, and pectins.

Table 2. Spring cereal grain and turnip variety and source.

Type	Variety	Company
Forage Oats	Everleaf	King's AgriSeeds
Barley	Robust	Lakeview Organics
Wheat	AC Barrie	SeCan
Triticale	Tritical® 718	King's AgriSeeds
Spelt	VNS	Lakeview Organics
Forage Turnip	Barkant	Barenbrug

VNS – variety not stated

LEAST SIGNIFICANT DIFFERENCE (LSD)

Variations in yield and quality can occur because of variations in genetics, soil, weather, and other growing conditions. Statistical analysis makes it possible to determine, whether a difference among varieties is real or whether it might have occurred due to other variations in the field. At the bottom of each table a LSD value is presented for each variable (i.e. yield). Least Significant differences (LSD's) at the 10% level of probability are shown. Where the difference between two treatments within a column is equal to or greater than the LSD value at the bottom of the column, you can be sure in 9 out of 10 chances that there is a real difference between the two varieties. Treatments that were not significantly lower in performance than the highest value in a particular column are indicated with an asterisk. In the example below A is significantly different from C but not from B. The difference between A and B is equal to 1.5 which is less than the LSD value of 2.0. This means that these varieties did not differ in yield. The difference between A and C is equal to 3.0 which is greater than the LSD value of 2.0. This means that the yields of these varieties were significantly different from one another. The asterisk indicates that B was not significantly lower than the top yielding variety.

Variety	Yield
A	6.0
B	7.5*
C	9.0*
LSD	2.0

RESULTS AND DISCUSSION

Seasonal precipitation and temperature recorded at a weather station in close proximity to Alburgh, VT is reported in Table 3. This season started off with above average rain in April and May. This delayed cereal grain planting into mid-May. Ideally planting would have been completed by April. Precipitation was below average during each harvest date.

Table 3. Seasonal weather data collected near Alburgh, VT 2011.

South Hero (Alburgh)	May	June	July	August
Average Temperature (F)	58.7	67.1	74.4	70.4
Departure from Normal	2.1	1.3	3.3	1.6
Precipitation (inches)	8.67	3.52	3.68	10.23
Departure from Normal	5.35	0.09	-0.29	6.38
Growing Degree Days (base 32)	826	1088	1314	1121
Departure from Normal	63.6	74.1	104	-26.3

Harvest Stage x Grain Species Interaction

For each parameter reported, there was a significant grain species by harvest stage interaction. This indicates that grain species did not perform the same across harvest stages. Yield increased for each treatment with later harvest stages except for spelt and triticale, where yield decreased from milk to soft dough. We would expect yield to increase as plants become more mature. A decline in yield may be attributed to drought conditions experienced in the summer months. Crude protein decreased with later harvest stages, except for barley and wheat, where protein levels stayed level from milk to soft dough. Fiber concentrations (ADF and NDF) were lowest during the vegetative stage for all the treatments except barley and wheat, where the lowest levels were seen in soft dough. This may be due to faster maturation of barley and wheat. These species may have been further along with fully developed grains when the treatments were sampled, which increased the overall quality.

Harvest Stage

Comparing treatments across harvest stage, forage yields were greatest, averaging 4396 lbs dry matter acre⁻¹, when harvested at soft dough (Table 4). Protein levels were highest during the vegetative stage. The lowest ADF levels were seen from the soft dough and vegetative harvest. Fiber content generally increases as plants mature but the formation of starch in the soft dough harvested grains may dilute the fiber content. The fiber digestibility (dNDF) was highest in the vegetative stage. The nonstructural carbohydrates were highest in the soft dough stage again a result of grain fill in the heads. There was no difference in the NeL (Mcal/lb) between vegetative and soft dough harvested forages. The additional starch from grain formation improves the overall quality of cereal grains harvested in the soft dough stage.

Table 4. Cereal grain yield and quality compared across harvest stages.

Stage	Moisture %	Yield lbs/acre	CP %	ADF %	NDF %	dNDF %	TDN %	NeL Mcal/lb	NSC %
Vegetative	81.7	1409	14.1	30.9*	50.2	68.8	63.7	0.658*	14.6
Milk	65.0	3724	10.7	33.8	56.5	48.7	61.6	0.635	17.1
Soft Dough	51.7	4396	10.0	30.7*	55.0	45.2	62.9	0.650*	21.1*
Trial Mean	66.1	3176	11.6	31.8	53.9	54.2	62.7	0.647	17.6
LSD (0.10)	1.70	367	0.48	1.25	1.76	1.35	0.77	0.0087	0.99

* Varieties with an asterisk indicate that it was not significantly different than the top performer (in bold).

Grain Species

Comparing treatments across species, forage oats yielded the highest at 4657 lbs dry matter acre⁻¹ (Table 5). Triticale, wheat, and spelt had the highest crude protein levels, between 11.6-12.3%. The barley treatments had the lowest ADF

levels and the highest total digestible nutrients (TDN), net energy of lactation (NEL), and non-structural carbohydrates (NSC). Fiber digestibility (dNDF) was greatest for the oat treatments. The addition of turnip into the seeding did not appear to impact quality. Overall, yields were similar or lower when turnips were added to the mix. A higher proportion of turnips may have resulted in higher CP and less fiber concentration but would also further decrease dry matter yields. Future work on seed mixes would help us better understand if this combination of forages is viable for the dairy community.

Table 5. Cereal grain yield and quality compared across species.

Treatment	Moisture %	Yield lbs/acre	CP %	ADF %	NDF %	dNDF %	TDN %	NeL Mcal/lb	NSC %
Barley	66.9	3668	11.1	28.0*	51.5	54.1	64.5*	0.667*	20.4*

* Varieties with an asterisk indicate that it was not significantly different than the top performer (in bold).

NS - None of the varieties were significantly different from one another.

Vegetative Stage Harvest

The vegetative stage harvest was to document the value of small grains as a potential early season grazing crop. The addition of turnip to the small grains had no statistical effect on the yield and quality parameters. At the vegetative stage harvest, the highest yielding treatments were barley + turnip (2294 lbs dry matter acre⁻¹), wheat, and barley (Table 6 and Figure 1). Triticale and spelt had the highest protein levels, over 15% concentration. Oats and triticale had the lowest ADF (Figure 2). ADF indicates the percent of highly indigestible plant material and values under 35% are desirable. The wheat treatments had the lowest digestible NDF values, whereas the oat treatments had the highest total digestible nutrients (TDN) and net energy of lactation (NeL) levels.

Table 6. Cereal grain yield and quality when harvested in the vegetative stage, June 27, 2011.

Vegetative stage	Moisture %	Yield lbs acre ⁻¹	CP %	ADF %	NDF %	dNDF %	TDN %	NeL Mcal/lb	NSC %
Barley	83.3	1920*	12.7	33.0	56.3	63.5	62.3	0.640	13.6

Figure 2. Neutral detergent fiber (NDF), acid detergent fiber (ADF), and non-structural carbohydrate (NSC) concentration of small grain forage harvested in the vegetative stage. *Treatments with the same letter did not differ significantly.

Milk Stage Harvest

Oats alone had the greatest dry matter yields when harvested in the milk stage, 5620 lbs dry matter acre⁻¹ (Table 7 and Figure 3). Wheat, triticale and oats had the highest milk stage protein levels, from 11.1 – 11.7%. The barley treatments had the lowest milk stage ADF and NDF levels (Figure 4), while oat, barley, and spelt had the highest digestible NDF levels. The barley treatments also had the highest total digestible nutrients, net energy of lactation and non-structural carbohydrates. Addition of turnips into the grain mix did not seem to impact forage quality.

Table 7. Small grain forage yield and quality harvested in the milk stage, mid-July, 2011.

Milk stage	Moisture %	Yield lbs acre ⁻¹	Protein %	ADF %	NDF %	dNDF %	TDN %	NeL Mcal/lb	NSC %
Barley	68.1*	4144	10.2	26.4*	49.9*	49.6*	65.4	0.680*	22.9*

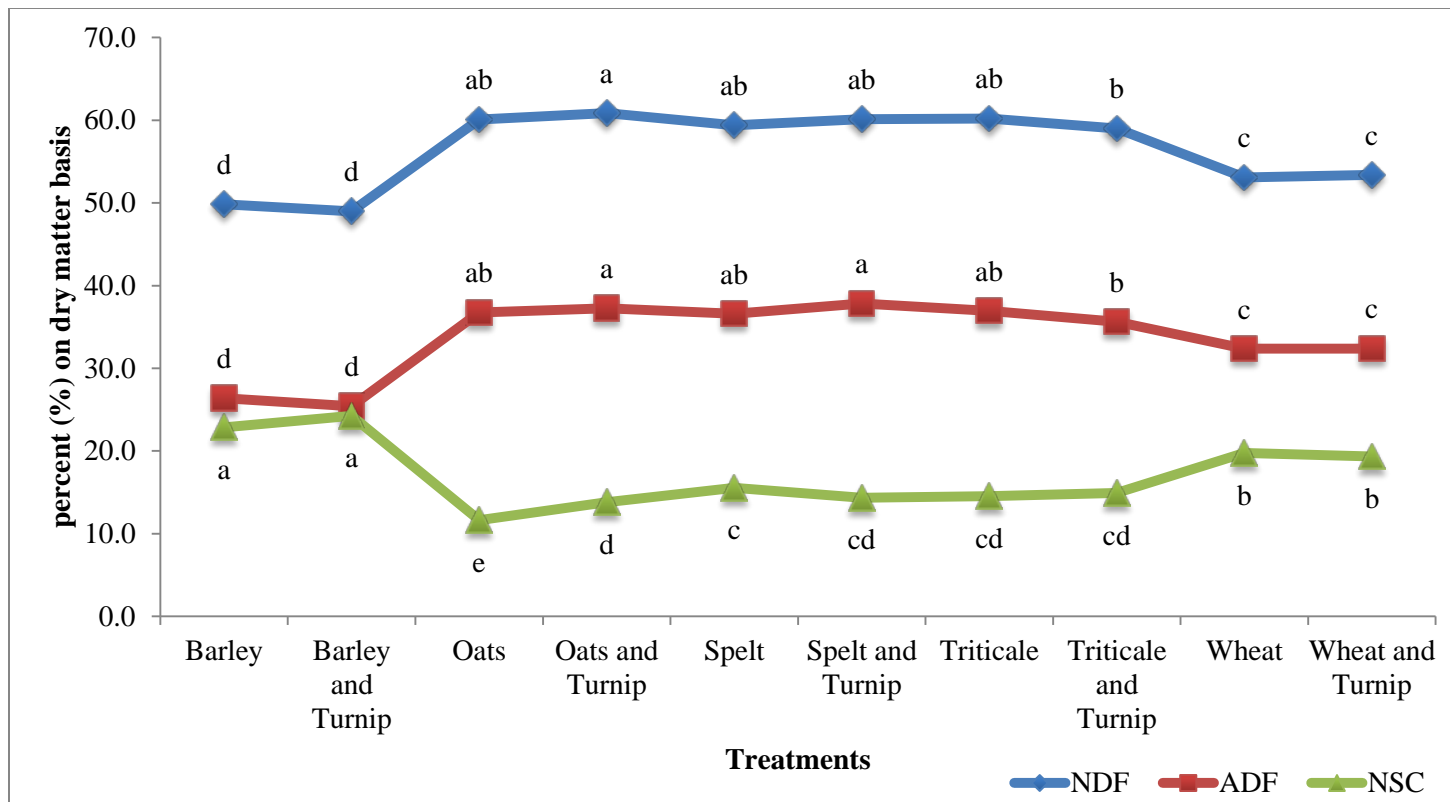

Figure 4. Neutral detergent fiber (NDF), acid detergent fiber (ADF), and non-structural carbohydrate (NSC) concentrations of small grain forage harvested in the milk stage. *Treatments with the same letter did not differ significantly.

Soft Dough Stage Harvest

Similar to the milk stage, oats alone were the highest yielding treatment when harvested during the soft dough stage (Table 8 and Figure 4). Oats yielded close to 7000 lbs dry matter acre⁻¹, which is about 2000 lbs acre⁻¹ more than the next highest yielding treatment, barley + turnip. Barley, spelt + turnip, triticale + turnip, and the wheat treatments had the highest protein levels of the soft dough harvest. The barley treatments were the highest quality treatments with the lowest ADF, NDF, and highest dNDF, TDN, NeL and NSC. Barley appears to be a good choice for high quality forage when harvested in the milk or soft dough stage. Oats were the highest yielding small grain forage when harvested in the milk or soft dough stage. In most cases turnips did not seem to provide much quality benefit to the forage. There was a slight decline in fiber concentrations but mostly not significant.

Table 8. Cereal grain yield and quality harvested at the soft dough stage, late-July, early-August 2011.

Soft dough stage	Moisture %	Yield lbs acre ⁻¹	Protein %	ADF %	NDF %	DNDF %	TDN %	NeL Mcal/lb	NSC %
